## 1.Introduction.

"Mathematics consists in proving the most obvious thing in the least obvious way." George Pólya.
Indeed, the mathematical literature abounds in clues and evidence in favour of Riemann's hypothesis [1]. One of these is the strict adherence to the hypothesis of billions of zeroes obtained by numerical evaluation. Limiting yourself to the accounting of the first zeros, regardless of their number, however, does not give any general property which enables to deduct for sure a rule for those coming next. Therefore, we are expanding the study by looking at all the points of the critical strip and in particular the bottom half of that band. The results brought to light in this way being general apply to the zeros themselves.

Our investigation is based on one among the analytical extensions of Riemann's series, the Dirichlet Eta function. It establishes the existence of a lower boundary for an indicative function of (positive) convexity deduced from it, resulting in the impossibility of symmetrical Riemann zeros on either side of the critical line.

Addressing a wide audience, many graphic illustrations are given here to make the thread of ideas as accessible and clear as possible. Despite all these additions, the article remains relatively short. Can its content then be worth a million of some other one ?

## 2.Analytic continuations.

Let us have $\mathrm{s}=\mathrm{a}+\mathrm{i} . \mathrm{b}$ some complex number.
The parameters $\mathrm{a}, \mathrm{b}$ and s are taken in the same context throughout this presentation.
The Riemann Zeta function is defined for $\operatorname{Re}(\mathrm{s})>1$ by the entire function :

$$
\begin{equation*}
\zeta(\mathrm{s})=\sum_{\mathrm{m}=1}^{\infty} \frac{1}{\mathrm{~m}^{\mathrm{s}}} \tag{1}
\end{equation*}
$$

The function diverges roughly in the form of an exponentially growing sinusoid for $\operatorname{Re}(\mathrm{s})<1$ for a given value of the parameter a , the real part of s , and the zeros of this function, called here (non-trivial) zeros of Riemann, correspond to numbers s such as the middle axis of this sinusoid aligns asymptotically with the axis $\mathrm{y}=0$.

Note that it is impossible to find precisely the zeros of this function by exploiting only this remark.
Riemann's Zeta function, however, admits, for $\operatorname{Re}(s)>0$, an analytical continuation based on Dirichlet's entire function Eta $\eta(\mathrm{s})$.

$$
\begin{equation*}
\eta(s)=\left(1-2^{1-s}\right) \cdot \zeta(s) \tag{2}
\end{equation*}
$$

This equality shows that the zeros of Dirichlet's Eta function are the union of zeros of 1-2 ${ }^{1-s}$ and zeros of Riemann's Zeta function. We call the first nominees, the Dirichlet's zeros.
So, we have the solutions sets :

$$
\begin{equation*}
\{\text { Eta function's zeroes }\}=\{\text { Dirichlet zeroes }\} \mathrm{U}\{\text { Riemann zeroes }\} \tag{3}
\end{equation*}
$$

The Dirichlet zeros are equal to

$$
\begin{equation*}
\mathrm{s}=1+\mathrm{i} .2 \pi . \mathrm{k} / \operatorname{Ln}(2) \tag{4}
\end{equation*}
$$

where k describes the relative integers Z .
These zeros, with constant real value ( $\mathrm{a}=1$ ), are genuine Siamese brothers of Riemann zeros as we showed in another article (see reference [[6]). The formers are inseparable from the latter and allow us to anticipate the behaviour of Riemann's zeros. They are the trivial image of the veracity of Riemann's hypothesis. Unsurprisingly, we will find them again the upcoming numerical illustrations and elsewhere in this text.

Let us now introduce the functional equation (see reference [2]) :

$$
\begin{equation*}
\zeta(s)=2^{s} \cdot \pi^{s-1} \cdot \sin (\pi \cdot \mathrm{~s} / 2) \cdot \Gamma(1-s) \cdot \zeta(1-s) \tag{5}
\end{equation*}
$$

This further analytical continuation introduces, due to the sinus, additional zeros -2 n , called trivial zeros, for any natural (thus positive) integer that are absent in previous functions. This last continuation is essential to our argument because we can state the following theorem :

## Theorem 1

The non-trivial Riemann zeros are symmetrical to the axis $s=1 / 2$ in the critical band.

## Proof

Let us have $\xi(\mathrm{s})=(1 / 2) . \mathrm{s} .(1-\mathrm{s}) \cdot \pi^{-\mathrm{s} / 2} \cdot \Gamma(\mathrm{~s} / 2) \cdot \zeta(\mathrm{s})$. We get (see reference [3]) immediately $\xi(\mathrm{s})=\xi(1-\mathrm{s})$.
Hence the theorem.

## Theorem 2

If the set of all Riemann's zeroes such as $0<\mathrm{a}<1 / 2$ is empty, then Riemann's zeros are all on the $1 / 2$ axis.

## Proof

This is a trivial consequence of theorem 1.
In 1896, Hadamard and La Vallée-Poussin3] independently proved that no zero could be on the $\operatorname{Re}(\mathrm{s})=1$ line, and therefore that all non-trivial zeros should be in the interior of the critical band $0<\operatorname{Re}(\mathrm{s})<1$. For this reason, we have chosen previously to write $0<a<1 / 2$ instead of $0 \leq a<1 / 2$, although this second way doesn't in any way hinder us here, quite the contrary, since it allows us to confirm the work of the authors cited simply by examining case a $=0$ (which is actually done in this article).

## 3.Explicit equations of the Dirichlet Eta function and more expressions.

Let us have $\operatorname{Ln}(x)$ the Napierian logarithm of $x$.
The Eta function writes as :

$$
\begin{equation*}
\eta(s)=\sum_{m=1}^{\infty} \frac{(-1)^{\mathrm{m}-1}}{\mathrm{~m}^{\mathrm{s}}} \tag{6}
\end{equation*}
$$

We thus get :

$$
\begin{equation*}
\eta(\mathrm{s})=\sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}-1} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \cos (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m}))+\mathrm{i} \cdot \sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}-1} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \sin (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m})) \tag{7}
\end{equation*}
$$

The search for $\eta(s)$ zeros is therefore tantamount to solving the two equations :

$$
\begin{equation*}
\sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}-1} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \cos (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m}))=0 \tag{8}
\end{equation*}
$$

and

$$
\begin{align*}
& \sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}-1} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \sin (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m}))=0  \tag{9}\\
&
\end{align*}
$$

Let us have

$$
\begin{equation*}
\mathrm{C} 0(\mathrm{a}, \mathrm{~b})=\sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}-1} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \cos (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m})) \tag{10}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathrm{S} 0(\mathrm{a}, \mathrm{~b})=\sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}-1} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \sin (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m})) \tag{11}
\end{equation*}
$$

Then the cancellation of $\eta(s)$ is equivalent to the following cancellation :

$$
\begin{equation*}
(\mathrm{C} 0(\mathrm{a}, \mathrm{~b}))^{2}+(\mathrm{S} 0(\mathrm{a}, \mathrm{~b}))^{2}=0 \tag{12}
\end{equation*}
$$

Let us have

$$
\begin{equation*}
\mathrm{D} 0(\mathrm{a}, \mathrm{~b})=(1 / 2) \cdot(\mathrm{C} 0(\mathrm{a}, \mathrm{~b}))^{2}+(\mathrm{S} 0(\mathrm{a}, \mathrm{~b}))^{2} \tag{13}
\end{equation*}
$$

## Theorem 3

If the partial second derivative of $\mathrm{D} 0(\mathrm{a}, \mathrm{b})$, versus parameter a , is strictly positive for $0 \leq a \leq 1 / 2$, then Riemann's hypothesis is true.

## Proof

Let us have some given $b$. Let us place ourselves at $a_{0}=1 / 2$. By our hypothesis, the second partial derivative versus $a$ is strictly positive in $\mathrm{a}_{0}-\varepsilon, \varepsilon>0$. The $\mathrm{D} 0(\mathrm{a}, \mathrm{b})$ function, positive or null as a sum of squares, is then convex (and therefore the first partial derivative is of constant sign). It necessarily increases on the constant $b$ line when a decreased from $a_{0}=-1 / 2$ to $\mathrm{a}=0$. The expression $\mathrm{D} 0(\mathrm{a}, \mathrm{b})$ can then be null only for $\mathrm{a}_{0}=1 / 2$.

We note the expressions of successive partial derivatives of $C 0(a, b)$ and $S 0(a, b)$ versus a as follows:

$$
\begin{equation*}
\operatorname{Ck}(\mathrm{a}, \mathrm{~b})=\sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}-1+\mathrm{k}} \cdot(\operatorname{Ln}(\mathrm{~m}))^{\mathrm{k}} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \cos (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m})) \tag{14}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{Sk}(\mathrm{a}, \mathrm{~b})=\sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}-1+\mathrm{k}} \cdot(\operatorname{Ln}(\mathrm{~m}))^{\mathrm{k}} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \sin (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m})) \tag{15}
\end{equation*}
$$

This allows us to write successive partial derivatives, versus a, of $\mathrm{D} 0(\mathrm{a}, \mathrm{b})$ as follows:

$$
\begin{equation*}
\mathrm{D} 1(\mathrm{a}, \mathrm{~b})=\mathrm{C} 0(\mathrm{a}, \mathrm{~b}) \cdot \mathrm{C} 1(\mathrm{a}, \mathrm{~b})+\mathrm{S} 0(\mathrm{a}, \mathrm{~b}) \cdot \mathrm{S} 1(\mathrm{a}, \mathrm{~b}) \tag{16}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathrm{D} 2(\mathrm{a}, \mathrm{~b})=\mathrm{C} 0(\mathrm{a}, \mathrm{~b}) \cdot \mathrm{C} 2(\mathrm{a}, \mathrm{~b})+\mathrm{S} 0(\mathrm{a}, \mathrm{~b}) \cdot \mathrm{S} 2(\mathrm{a}, \mathrm{~b})+(\mathrm{C} 1(\mathrm{a}, \mathrm{~b}))^{2}+(\mathrm{S} 1(\mathrm{a}, \mathrm{~b}))^{2} \tag{17}
\end{equation*}
$$

Our objective is to prove that $\mathrm{D} 2(\mathrm{a}, \mathrm{b})>0$ for $0 \leq \mathrm{a} \leq 1 / 2$.
There is a trivially positive part to $\mathrm{D} 2(\mathrm{a}, \mathrm{b})$ that is $\mathrm{P} 2(\mathrm{a}, \mathrm{b})=(\mathrm{C} 1(\mathrm{a}, \mathrm{b}))^{2}+(\mathrm{S} 1(\mathrm{a}, \mathrm{b}))^{2}$. It ought to be compared to the complementary part $Q(a, b)=C 0(a, b) \cdot C 2(a, b)+S O(a, b) \cdot S 2(a, b)$. As long as $Q(a, b)$ is positive, everything is fine. If $Q(a, b)$ is negative and we have $|\mathrm{Q}(\mathrm{a}, \mathrm{b})|<\mathrm{P}(\mathrm{a}, \mathrm{b})$, then the $\mathrm{D} 2(\mathrm{a}, \mathrm{b})$ expression remains positive and Riemann's hypothesis stems from it. It is therefore wise to examine the evolution within the lower critical band of the ratio :

$$
\begin{equation*}
\mathrm{R} 2(\mathrm{a}, \mathrm{~b})=\frac{\mathrm{C} 0(\mathrm{a}, \mathrm{~b}) \cdot \mathrm{C} 2(\mathrm{a}, \mathrm{~b})+\mathrm{S} 0(\mathrm{a}, \mathrm{~b}) \cdot \mathrm{S} 2(\mathrm{a}, \mathrm{~b})}{(\mathrm{C} 1(\mathrm{a}, \mathrm{~b}))^{2}+(\mathrm{S} 1(\mathrm{a}, \mathrm{~b}))^{2}} \tag{18}
\end{equation*}
$$

From this argument results the following theorem equivalent to theorem 3 :

## Theorem 4

If $\mathrm{R} 2(\mathrm{a}, \mathrm{b})>-1$ for $0 \leq \mathrm{a} \leq 1 / 2, \mathrm{~b}$ any given real number, then Riemann hypothesis is true.

## Note

This is a sufficient (and not necessary) condition : A contradictory b (giving R2(a,b) $\leq-1$ ) only excludes the desired result in that value $b$ and its immediate vicinity. We will see below that, indeed, there are $b$ values such as the expression $R 2(a, b)$
is less than the -1 value, for $0 \leq \mathrm{a} \leq 1 / 2$, near the origin to abscissas smaller than that of the first Riemann zero (and the first Dirichlet zero).

It should also be noted that because of the symmetry of the functional equation, we only look at the $b \geq 0$ values, the arguments being in any way identical to $\mathrm{b} \leq 0$ case.

## 4.Numerical illustrations.

The reader will refer to Appendix 1 for the conditions to ensure the consistency and accuracy of numerical assessments. All illustrations are given with an interval between points equal to $\Delta \mathrm{b}=1 / 10$ when not otherwise specified.

The study concerns the critical half-band $0 \leq \mathrm{a} \leq 1 / 2$. However, as Riemann's zeros, at least for those known, are all on the critical line $a=1 / 2$, the highlighted expressions are necessarily at their climax and therefore the most prominent on this critical line. Thus, the reader will not be surprised if some calculations focus solely on this line. On a parallel line < $1 / 2$ of the critical band, the situation is similar but rapidly with a (very) smaller magnitude.

The content of this paragraph 4, called as "illustrations", as well as Appendix 8, contains a set of relationships that are sufficient to show the evidence of the hypothesis. This evidence is overwhelming, the zeros and the neighbourhoods of these zeroes offering only a paroxysm. However, the proof of these relations, for the current paragraph except for the indispensable part 4.1, would surely be a real "tour de force" and is not undertaken here. Hence the obvious need for paragraph 5 that will follow it.

### 4.1 Staggering of the sums of squares $\operatorname{SCk}(a, b)$.

We compare the functions based on sums of $\operatorname{Ck}(a, b)$ and $\operatorname{Sk}(a, b)$ squares, the latter being defined from relationships (14) and (15) :

$$
\begin{equation*}
\operatorname{SCk}(\mathrm{a}, \mathrm{~b})=(\operatorname{Ck}(\mathrm{a}, \mathrm{~b}))^{2}+(\operatorname{Sk}(\mathrm{a}, \mathrm{~b}))^{2} \tag{19}
\end{equation*}
$$

The graphics representations clearly show that, above $b \approx 20$, the $\mathrm{SC}_{\mathrm{k}+1}(\mathrm{a}, \mathrm{b})$ curves are above the $\operatorname{SC}_{\mathrm{k}}(\mathrm{a}, \mathrm{b})$ curves in relatively nesting positions.
(100000

We get immediately :

## Theorem 5

We have almost everywhere :

$$
\begin{equation*}
\mathrm{SC}_{\mathrm{k}+1}(\mathrm{a}, \mathrm{~b})>\mathrm{SC}_{\mathrm{k}}(\mathrm{a}, \mathrm{~b}) \tag{20}
\end{equation*}
$$

## Note 1:

The curves are given with our standard step $\Delta b=1 / 10$. The downwards peaks are not necessarily fully formed here. Nevertheless, one can see clearly the peak of $\operatorname{SC1}(a, b)$ at the level of Riemann's zero corresponding to $b \approx 5010,9331981$. The nesting does not prevent in any way to have, close to the Riemann zeros, very small values for $\mathrm{SC}_{\mathrm{k}}(\mathrm{a}, \mathrm{b})$, whatever k $>0$, and this especially for $\operatorname{SC1}(\mathrm{a}, \mathrm{b})=(\mathrm{C} 1(\mathrm{a}, \mathrm{b}))^{2}+(\mathrm{S} 1(\mathrm{a}, \mathrm{b}))^{2}$. This effectively allows us to find increasingly larger $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ values here or there, since $\operatorname{SC} 1(a, b)$ is the denominator of that expression.

## Note 2:

The terminology "almost everywhere" is not that of the probability theory. The term only means very often, thus without a strict notion of density, as the study is not completed at this stage.

To improve accuracy, two parameters are to be taken into account:

- The number of terms of the truncation
- The step $\Delta \mathrm{b}$

In the graphs below, at the peaks' levels, $\Delta \mathrm{b}$ is taken here equal to $1 / 10000$. For SC 0 , at Riemann's zeros level, both peaks take on lower and lower values (since the theoretical limit here is 0 ). For SC1, the peak progresses to lower values between truncation with 10,000 terms up to 50,000 terms. This progression then stops. The minimum value statements are 0.00097147 for 10000 terms, 0.00053732 for 50000 terms, 0.00058222 for 150000 terms, nothing in fact prohibiting a higher value in the final instance when accuracy increases.

We see above the attraction that constitutes two narrow peaks for $\mathrm{SC}_{\mathrm{k}}(\mathrm{a}=1 / 2, \mathrm{~b})$ on the expression $\mathrm{SC}_{\mathrm{k}+1}(\mathrm{a}=1 / 2, \mathrm{~b})$ in the hereby $\mathrm{k}=0$ case. As two peaks create a peak above them, the phenomenon may occur frequently only up to the $\operatorname{SC}(1 / 2, b)$ level. An imposing peak for $\operatorname{SC} 2(1 / 2, b)$ is certainly rare, requiring 3 very close Riemann zeros. A significant spike is undoubtedly exceptional when $\mathrm{k}>2$.

## Theorem 6

We have

$$
\begin{equation*}
\mathrm{SC}_{\mathrm{k}+1}(\mathrm{a}, \mathrm{~b})>\mathrm{SC}_{\mathrm{k}}(\mathrm{a}, \mathrm{~b}) \tag{21}
\end{equation*}
$$

## Proof

The numerical study clearly shows that the inequality is true except possibly near the peaks' positions and moreover the critical case to examine is that of the relative position of $\operatorname{SC} 0(\mathrm{a}, \mathrm{b})$ and $\operatorname{SC} 1(\mathrm{a}, \mathrm{b})$, higher k cases being even more obvious. So, let us place ourselves at a peak for $\operatorname{SC1}\left(\mathrm{a}, \mathrm{b}_{\text {peak }}\right)$. The expression $\operatorname{SC} 0\left(\mathrm{a}, \mathrm{b}_{\text {peak }}\right)$ presents at this abscissa a partial derivative, versus $b$, close to 0 . It can be written, with the notations of paragraph $5.2, \partial_{\mathrm{b}}\left((\mathrm{C} 0(\mathrm{a}, \mathrm{b}))^{2}+(\mathrm{S} 0(\mathrm{a}, \mathrm{b}))^{2}\right)=$ $2(C 0(a, b) \cdot S 1(a, b)-S 0(a, b) \cdot C 1(a, b))$ with value to take $a t b=b_{\text {peak }}$. Hence the approximate equality $C 0\left(a, b_{\text {peak }}\right) \cdot S 1\left(a, b_{\text {peak }}\right) \approx$ $\mathrm{S} 0\left(\mathrm{a}, \mathrm{b}_{\text {peak }}\right) \cdot \mathrm{C} 1\left(\mathrm{a}, \mathrm{b}_{\text {peak }}\right)$. Let us simplify the entries by failing to repeat the coordinates ( $\mathrm{a}, \mathrm{b}_{\text {peak }}$ ). The C 0 and S 0 functions are non-zero since they are not placed at a Riemann zero. We then have at the peak of SC1, the ordinate difference between SC 1 and SC 0 equal to $\mathrm{C} 1^{2}+\mathrm{S}^{2}-\left(\mathrm{C} 0^{2}+\mathrm{S} 0^{2}\right) \approx(\mathrm{C} 0 \cdot \mathrm{~S} 1 / \mathrm{S} 0)^{2}+\mathrm{S}^{2}-\left(\mathrm{C} 0^{2}+\mathrm{S} 0^{2}\right)=\left((\mathrm{S} 1 / \mathrm{S} 0)^{2}-1\right) .\left(\mathrm{C} 0^{2}+\mathrm{S} 0^{2}\right)$, and in the same way,
$\mathrm{C}^{2}+\mathrm{Sl}^{2}-\left(\mathrm{C} 0^{2}+\mathrm{S}^{2}\right) \approx\left(\mathrm{C} 1^{2}+(\mathrm{C} 1 \cdot \mathrm{~S} 0 / \mathrm{C} 0)^{2}-\left(\mathrm{C} 0^{2}+\mathrm{S} 0^{2}\right)=\left((\mathrm{C} 1 / \mathrm{C} 0)^{2}-1\right) \cdot\left(\mathrm{C} 0^{2}+\mathrm{S}^{2}\right)\right.$. These expressions, as sums of continuous functions, are continuous. Thus, for the difference $\mathrm{C}^{2}+\mathrm{S}^{2}-\left(\mathrm{C} 0^{2}+\mathrm{S}^{2}\right)$ to become negative, it must first be able to go to zero. The coordinate point ( $\mathrm{a}, \mathrm{b}_{\text {peak }}$ ) being intermediate between two Riemann zeros, we have $\mathrm{C} 0^{2}+\mathrm{S} 0^{2} \neq 0$. This means that the nullity of $\mathrm{C}^{2}+\mathrm{S}^{2}-\left(\mathrm{C} 0^{2}+\mathrm{S} 0^{2}\right)$ results in the joint nullity of $(\mathrm{C} 1 / \mathrm{C} 0)^{2}-1$ and $(\mathrm{S} 1 / \mathrm{S} 0)^{2}-1$, or simultaneously $\mathrm{C} 1 \rightarrow \mathrm{C} 0$ and $\mathrm{S} 1 \rightarrow \mathrm{~S} 0$ near the abscissa of the peak. However, C 0 is by no means C 1 , nor S 0 compares to S 1 and the ratio of their numerical values does not converge due to small, near-random values of C0, S0, C1 and S1. Small values of C0 and S0 are directly linked to small value of the difference $\mathrm{Cl}^{2}+\mathrm{Sl}^{2}-\left(\mathrm{C}^{2}+\mathrm{SO}^{2}\right)$, creating an increasing oscillation (and therefore a divergence). At the limit $\mathrm{SC} 1 \rightarrow \mathrm{SC} 0$, the oscillation tends towards infinity making equality impossible.

We give the example for the peak near to $\mathrm{b}_{\text {peak }} \approx 7005.08168$, the phenomenon of oscillations being reproducible with any other example. We do have $\mathrm{C}^{2}+\mathrm{S}^{2}-\left(\mathrm{C} 0^{2}+\mathrm{S} 0^{2}\right) \rightarrow 0$ (see graphic 6 ). But $(\mathrm{C} 1 / \mathrm{C} 0)^{2}-1 \approx(\mathrm{~S} 1 / \mathrm{S} 0)^{2}-1 \approx 58$ (which is a first handicap) as long as we take a truncation between 800 and 2300 terms, case where $\mathrm{C}^{2}+\mathrm{S} 1^{2}-\left(\mathrm{C} 0^{2}+\mathrm{S} 0^{2}\right)$ does not yet converge towards 0 . When this convergence finally begins with the sufficient number of terms (here above 2500), the ratios $\mathrm{C} 1 / \mathrm{C} 0$ and $\mathrm{S} 1 / \mathrm{S} 0$ enter an unstable phase due to the low values of $\mathrm{C} 0, \mathrm{~S} 0, \mathrm{C} 1$ and S 1 (graphics 7 and 8 ) oscillating around the previous value. This oscillation remains regardless of the number of terms, and therefore to infinity, that is up to the effective value of $\mathrm{Cl}^{2}+\mathrm{Sl}^{2}-\left(\mathrm{C}^{2}+\mathrm{S}^{2}\right)$.

## Theorem 7

We have for $0 \leq \mathrm{a} \leq 1 / 2$ and $\mathrm{k}>0$ :

$$
\begin{equation*}
\mathrm{SC}_{\mathrm{k}}(\mathrm{a}, \mathrm{~b})>0 \tag{22}
\end{equation*}
$$

## Proof

This is immediately due to theorem 6.

## Note:

The SC0 ordinate at the intermediate abscissa $b_{\text {peak }}$ is, a priori, statistically lower as two Riemann zeros are closer. We return to this point in paragraph 4.5.

### 4.2 Current values of R2(a,b).

We represent the $R 2(a, b)$ ratio as a function of parameter $a$ for fixed $b$. The view below shows the evolution starting from $a=1 / 2$ (background of the image) with alternating of downwards peaks and upwards peaks. At $a=1 / 2$, the ordinate is null for Riemann and Dirichlet zeroes. The condition of cancellation of $\mathrm{C} 0(\mathrm{a}, \mathrm{b}) \cdot \mathrm{C} 2(\mathrm{a}, \mathrm{b})+\mathrm{S} 0(\mathrm{a}, \mathrm{b}) \cdot \mathrm{S} 2(\mathrm{a}, \mathrm{b})$ is more general and may occur without the presence of these two types of zeros. The fifth peak upwards is less marked. It corresponds to the vicinity of the 166 th Dirichlet zero $(166 * 2 \pi / \operatorname{Ln}(2) \approx 1504.743567)$.

In the graphics that follow, the b values are taken in $\mathbb{N}$ for 100 consecutive values. Some b values may be close to the imaginary values of Riemann or Dirichlet zeroes.
The range of $b$ values is given in the legend. The min and max values shown are those of $R 2(a, b)$ at $a=1 / 2$. These are of course neither the absolute minimums nor the absolute maximums if $b \in \Re$.

There is some chaos in the variations of $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ when $\mathrm{a}>1 / 2$, but the trend towards the asymptotic value $\mathrm{R} 2(\mathrm{a} \rightarrow-\infty, \mathrm{b})$ $\rightarrow 1$ is quickly activated on the side $\mathrm{a} \leq 1 / 2$, hence the obvious interest in choosing this side of the critical band.
The graphics below give the values of $\mathrm{R} 2(\mathrm{a}=1 / 2, \mathrm{~b})$ of the previous series of b numbers. The first graphic is for b in ascending order. The second graphic are the same values where $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ are sorted in ascending order (the x axis becoming arbitrary).

The latest graphic shows that the increase in $b$ has no real impact on the order of the distributions of the $\mathrm{R} 2(1 / 2, b)$ values and in particular on its minimum value. The last curve of the legend, where $b$ is in the 100001 to 100100 value range, is simply intermediate to the other distributions. We go back to the shape of the latter graphic with increased precision in the following paragraph.

### 4.3 Random surveys of $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$.

We start with surveys for $\mathrm{a}=1 / 2$.
We are talking about random surveys although $b$ is taken with constant spacing 1. Indeed, the value that $R 2(a, b)$ versus $b$, for given parameter $a$, is not predictable: Riemann's zeroes have $b_{r}$ imaginary abscissas that we can call random and the value of R2(a,b) for constant $b$ spacing will be at a random distance of the nearby $b_{r}$ therefore having seemingly random $R 2(a, b)$. The same is true of minimums and maximums of R2(a,b) or any other choice. Taking $b$ with random or constant distances thus amounts to the same if we want to statistically analyse the distribution of R2(a,b) given some parameter a.

We then have the following incomplete table :

## Table 1

| $\mathrm{b}-\mathrm{k} .10000$ | $\mathrm{R} 2(1 / 2,0 \leq \mathrm{b}<9999)$ <br> $\mathrm{k}=0$ | $\mathrm{R} 2(1 / 2,10000 \leq \mathrm{b}<19999)$ <br> $\mathrm{k}=1$ | $\mathrm{R} 2(1 / 2,20000 \leq \mathrm{b}<29999)$ <br> $\mathrm{k}=2$ |
| :---: | :---: | :---: | :---: |
| 0 | -1.08934023 | -0.05235938 | 0.53967998 |
| 1 | -1.22982782 | -0.24315523 | 0.37783264 |
| 2 | -1.23743739 | 0.92023095 | 1.18166428 |
| 3 | -0.59258188 | -0.00324345 | 0.43683645 |
| $\ldots$ | $\ldots$ | $\ldots$ | $\ldots$ |
| 9997 | 1.10427165 | 0.91778738 | 0.51817126 |
| 9998 | -0.02703119 | -0.11687438 | 0.83313405 |
| 9999 | 0.26809106 | 1.49868353 | 2.16119046 |

These values are then sorted in ascending order, with the reference axis becoming a mere index.

## Table 2

| i | $\mathrm{R} 2(1 / 2,0 \leq \mathrm{b}<9999)$ | $\mathrm{R} 2(1 / 2,10000 \leq \mathrm{b}<19999)$ | $\mathrm{R} 2(1 / 2,20000 \leq \mathrm{b}<29999)$ |
| :---: | :---: | :---: | :---: |
| 0 | -1.237437394 | -0.367149358 | -0.415532661 |
| 1 | -1.22982782 | -0.336819688 | -0.389586665 |
| 2 | -1.089340232 | -0.319879054 | -0.33263088 |
| 3 | -0.592581881 | -0.314646353 | -0.312157279 |
| $\ldots$ | $\ldots$ | $\ldots$ | $\ldots$ |
| 9997 | 7.164445983 | 11.20934744 | 13.13029216 |
| 9998 | 10.87793755 | 12.42906401 | 13.19809132 |
| 9999 | 11.3992441 | 21.28605665 | 16.7790967 |

The curves that are representative of the distributions of values obtained in this way are :

The shape curves in the central part are the same for the three sorted data choices.
It would be the same for any other random choice of abscissas provided that the selected sample has sufficient elements. This random choice may be a $\Delta \mathrm{b}$ spacing different from 1 .

Below are the $R 2(a, b)$ results for a smaller range of values $(b \in[500,750])$ and a smaller spacing $\Delta b(\Delta b=1 / 100)$. The curve's shape for $\mathrm{a}=1 / 2$ (in yellow) is the same. Again, the x -axis is not really b since the values of $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ have been taken up in ascending order.

As the parameter a decreased progressively getting closer to 0 , the set of $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ values get closer to the horizontal axis of ordinate 1 .

The graphic below provides a close-up view for the part we are particularly interested in, that is when $\mathrm{R} 2(\mathrm{a}, \mathrm{b})<0$. The curves show up in descending order of a values as one would expect. Here, for $\mathrm{a}=0.55$, we still have $\mathrm{R} 2(\mathrm{a}, \mathrm{b})>-1$, but this is no longer the case for $\mathrm{a}=0.6$ (which is without any prejudice for our study for which the proof is necessary only in $a \in[0,1 / 2])$.

### 4.4 Relations between local minimum and maximum of $\mathbf{R 2}(\mathbf{a}, \mathrm{b})$.

The $\mathrm{R}(\mathrm{a}=1 / 2, \mathrm{~b})$ function changes from local minimum to local maximum when b increases. Here we are looking for some relationships between a maximum and the two minima that frame it.

The graphic below gives a sample of the values taken by $\mathrm{R} 2(1 / 2, b)$ for $b \in[15000,15250]$. The savvy reader may note, although this is not very visible, that a (positive) peak also corresponds to negative value spikes on either side of this peak.

This is more visible by making some magnifications :

It is as if the rise towards the high values $r_{\text {peak }}$ of $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ requires a spring force acting from under ordinate 0 . Indeed, the higher a peak is, the higher the negative values $r_{\text {low }}$ surrounding it.

Graphic23 however shows "high" negative values on both sides that do not necessarily cause a high (positive) spike when their forces are already affected in nearby peaks.
Thus, if we represent $r_{\text {peak }}$ as a function of $r_{M}$, where $r_{p e a k}$ is the value of a given peak, $r_{M}$ the average between the two lower values on either side, we necessarily get a "parasitic" branch.
This is what is shown in the graphics (24) below.
The reader will note that these two graphics (which are the same data except a logarithmic scale for the $y$-axis in the second graphic) were made by aggregating the data provided in intervals $b \in[3000,3250],[6000,6250],[9000,9250],[12000$, $12500],[15000,15250]$ with a $\Delta \mathrm{b}=1 / 100$ step.

The "parasitic" branch is the one extending horizontally. It does not provide any additional useful information to that provided by the ascending branch since it is linked to it. The downside is that it can give the illusion that the abscissa rM
is not bounded when what determines it is actually the evolution of the ascending branch. In paragraph 4.5 , we specify the criterion after which the mix of horizontal and ascending branches take an overriding character.

The illustration, based on graphic 24 , leads also to an important remark. The $\Delta \mathrm{b}=1 / 100$ step remains too wide to get a good accuracy of the actual values of the peaks $r_{\text {peak }}$. It is imperative to do a point-by-point study. We thus provide in Appendix 3 Table 7 the complete data of the graphics below (which are again the same data with simply a logarithmic scale for the $y$-axis in the second chart).

The points on the first graphic show an increasingly rapid divergence beyond abscissa $\mathrm{rM} \approx-0.35$. The second graphic shows that this increase is over-exponential. The data near the origin are more erratic because of the combination of the ascending and horizontal branches within graphic (24).

The interpolation function used here is :

$$
\begin{equation*}
\mathrm{r}_{\text {peak }} \approx \frac{1.4}{\left(0.5+\mathrm{r}_{\mathrm{M}}\right)^{2,1}}-5 \tag{23}
\end{equation*}
$$

The adjustment parameters are very approximate (except 0.5 which is certainly near effective value). We incline for an exponent with denominator equal to 2 , but our data to date indicates the adjustment proposed here. For lack of better, we let it that way.

The important point is that this approximation function diverges at $\mathrm{r}_{\mathrm{M}}=-0.5$ which means a bumper value impossible to exceed (as soon as -0.5 instead of -1 ) because of the continuity of $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ demonstrated in paragraph 5.1. This then confirms theorem 4.

Note: The term $\mathrm{r}_{\mathrm{M}}$ is an average of 2 terms. Nothing prevents one of them from being smaller than -0.5 . Cependant les deux coordonnées $r_{\text {bas }}$ autour d'un pic étant à l'extérieur de part en d'autre des deux zéros de Riemann, et donc telles que $r_{\text {bas }}<0$, la limite $r_{M}>-0,5$ signifie qu'aucun des deux $r_{\text {bas }}$ ne peut être inférieur à -1 . However, since the two $r_{\text {low }}$ coordinates around a peak are outside on either side of the two Riemann zeros, and therefore such that $\mathrm{r}_{\text {low }}<0$, the limit $\mathrm{r}_{\mathrm{M}}>-0.5$ means that neither of the two $\mathrm{r}_{\text {low }}$ can be less than -1 .

### 4.5 Relationship between Riemann zeros spacings and R2(a,b).

A random search for high-amplitude peaks of R2(a,b) would require enormous computational resources without the existence of a sufficiently simple tracking. Fortunately, there is a link between the gap of two consecutive Riemann zeros and the height of the intermediate peak, a link that then makes the search quite easy thanks to the database referenced in [5].

As it turns on, a peak is generally all the more ample as the gap between two consecutive Riemann zeros (at abscissas noted zero_R- and zero_R+) is smaller. We have the following approximate relationship, where $b_{r}$ is the peak abscissa, $\Delta \mathrm{b}_{\mathrm{r}}$ the gap between two Riemann's zeroes. The reader will find the numerical elements in Appendix 5 :

$$
\begin{equation*}
\mathrm{r}_{\text {peak }} \approx 1+\frac{5}{\Delta \mathrm{br}^{2} \cdot \mathrm{br}^{1 / 4}} \tag{24}
\end{equation*}
$$

According to this relationship, the amplitude of the peak tends towards infinity when the gap tends towards zero. These cases are necessarily more and more common for very high-value abscissas since the average difference between zeros is asymptotically in $2 \pi / \operatorname{Ln}$ (abs_zeroR). The presence of the logarithm, however, makes it difficult to find many cases with very high values here. In particular there is no $r_{\text {peak }}>10000$ for the first 500,000 Riemann zeroes.

The first graph below represents the numerical results and evaluation by an interpolation formula without taking into account the abscissa of the peak $\mathrm{br}\left(\mathrm{br}^{1 / 4}\right.$ term at denominator obliterated). In the second, this additional factor is introduced.
100000

The reader will find in appendix 8 a more comprehensive study of the $r_{\text {peak }}$ approximation's functions enabling a better picture of the actual value of these extremums.

For large peaks, we can neglect the constants -5 and 1 in the relations 23 and 24 In order to compensate for the power 2.1 that we reduce to 2 , we increase somewhat the constant in front of the fraction to obtain $r_{\text {peak }} \approx 1.8 /\left(0.5+r_{M}\right)^{2} \approx 5 / \Delta b_{r}{ }^{2} \cdot b_{r}{ }^{1 / 4}$. This results in :

$$
\begin{equation*}
\mathrm{r}_{\mathrm{M}} \approx-(1 / 2) \cdot\left(1-1,2 \cdot \Delta \mathrm{~b}_{\mathrm{r}} \cdot \mathrm{br}^{1 / 8}\right) \tag{25}
\end{equation*}
$$

Since $\Delta b_{r} \cdot b_{r}^{1 / 8}>0$, the term $r_{M}$ is greater than -0.5 .
For values close to $0, \exp (-x) \approx 1-x$, and thus :

$$
\begin{equation*}
r_{M} \approx-(1 / 2) \cdot \exp \left(-1,2 \cdot \Delta b_{r} \cdot b_{r}{ }^{1 / 8}\right) \tag{26}
\end{equation*}
$$

In the range of numerical values examined, we also have the simpler alternative formula :

$$
\begin{equation*}
\mathrm{r}_{\mathrm{M}} \approx-(1 / 2) \cdot \exp \left(-5 \Delta \mathrm{~b}_{\mathrm{r}}\right) \tag{27}
\end{equation*}
$$

which leads to the following graphs:

The alignment of the points clearly stalls for a gap between Riemann zeroes larger than $\Delta \mathrm{b}_{\mathrm{r}}=1 / 2$ (and therefore apparently regardless of the abscissas of these zeroes). Based on this approximate critical value, as the data in Appendix 5 seems to
show, the order of abscissas abs_r $r_{\text {low }}$ (abscissa $b$ of $r_{M}$ before the peak), abs_zero_R- (abscissa of Riemann's zero before the peak), abs_peak (abscissa of the peak), abs_zero_R+ (abscissa of the Riemann zero after the peak), abs_r ${ }_{\text {high }}$ (abscissa of $r_{M}$ after the peak), is no longer respected (which is perfectly possible since the cancellation of R2(a,b) does not correspond to the cancellation of $(\mathrm{C} 0(\mathrm{a}, \mathrm{b}))^{2}+(\mathrm{SO}(\mathrm{a}, \mathrm{b}))^{2}$.

Below the critical value of the gap, the points align perfectly here, the only selection criterion having been to take the gap $\Delta b_{r}$ among the first 100,000 zeroes such as $\Delta b_{r}$ is closest by higher value of $0.05,0.10,0.15,0.20,0.25,0.30,0.35,0.40$ and 0.45 , (for the construction of graphic 29), a selection that gives only an almost uniform spacing in abscissa but in no way any predisposition on the value of the ordinate. We have also added to the chart the lower $\Delta \mathrm{b}_{\mathrm{r}}$ gap solution that exists among Riemann's first 500000 zeroes.

It should be noted that the value of the abscissa abs_peak does not intervene in the proposed formula (unlike the relationship involving $r_{\text {peak }}$ ). Close to the origin ( $\Delta b_{r}<0.05$ ), the relationship 27 is quasi-linear by developing $\exp (x)$ to the first order and clearly tends (cf. graphic 30) towards the limit $\mathrm{r}_{\mathrm{M}}=-1 / 2$.

### 4.6 Geodesics of R2(a,b).

We adopt the word "geodesic" out of sheer convenience. These are more specifically the local extrema of the R2(a,b) function.

## Theorem 8

The local maximum value of $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ is related to the minimums' paths in the vicinity of this peak.

## Proof

The extremums of $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ are determined by the cancellation of the two partial derivatives $\partial_{\mathrm{a}} \mathrm{R} 2$ and $\partial_{\mathrm{b}} \mathrm{R} 2$. This means using relations (30) and (31) that we will establish later on :

$$
\begin{aligned}
& \left(\mathrm{C}^{2}+\mathrm{S} 1^{2}+2 \mathrm{C} 0 \cdot \mathrm{C} 2+2 \mathrm{~S} 0 . \mathrm{S} 2\right) \cdot(\mathrm{C} 1 . \mathrm{C} 2+\mathrm{S} 1 . \mathrm{S} 2)+\left(\mathrm{C1}^{2}+\mathrm{S} 1^{2}\right) \cdot(\mathrm{C} 0 \cdot \mathrm{C} 3+\mathrm{S} 0 . \mathrm{S} 3)=0 \\
& \left(\mathrm{C}^{2}+\mathrm{S} 1^{2}+2 \mathrm{C} 0 . \mathrm{C} 2+2 \mathrm{~S} 0 \cdot \mathrm{~S} 2\right) \cdot(\mathrm{C} 1 . \mathrm{S} 2-\mathrm{S} 1 . \mathrm{C} 2)+\left(\mathrm{C}^{2}+\mathrm{S} 1^{2}\right) \cdot(\mathrm{S} 0 . \mathrm{C} 3-\mathrm{C} 0 \cdot \mathrm{~S} 3)=0
\end{aligned}
$$

Thus

$$
\begin{equation*}
(\mathrm{C} 1 . \mathrm{C} 2+\mathrm{S} 1 . \mathrm{S} 2) .(\mathrm{S} 0 . \mathrm{C} 3-\mathrm{C} 0 . \mathrm{S} 3)=(\mathrm{C} 1 . \mathrm{S} 2-\mathrm{S} 1 . \mathrm{C} 2) .(\mathrm{C} 0 . \mathrm{C} 3+\mathrm{S} 0 . \mathrm{S} 3) \tag{28}
\end{equation*}
$$

This equation is common to local minimums and maximums, hence the link.

## Note 1.

The common equation explains the link between a peak of R2(a,b) and the two minima on either side of that peak observed in the illustrations in the previous paragraph. In fact, what produces the value of the peak is not only the two values on either side, where the parameter a is set in advance, but the entire minimum geodesic "surrounding" that peak. However, the average of the two values examined above is already, when the peak has a significant value above 1 , a good representation of the said neighbourhood and thus allows to anticipate the peak value.

## Note 2.

The minimums on both sides must have comparable values for the approximation equation to be useful. When this is the case, for a high-value peak, the configuration of the minima (in dark blue) is cross-shaped as in graphic 31, while the altitude isopleths tend vertically as shown by the example of graphic 32 .

When the minimums values are dissimilar, the two wings of the minimums are instead oriented in the opposite direction on the side of the extremum with value close to -0.5 and generally horizontal on the side of the other minimum. The altitude isopleths tend horizontally. The graphics that illustrate this point are numbered 33 and 34 .
This explains the "parasitic" branch.
In addition, the peak is only its initial draft at $\mathrm{a}=0.5$ and continues to increase on the side of $\mathrm{a}>0.5$ (pink line below).

Note 3.
The uncompromising reader will object that an equation such as the relationship 28 can be found not only for geodesics but for any value one wishes to affix to $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ and therefore proves nothing. We are not saying the contrary for the first part of this argument. Indeed, no point escapes the equations of the whole set of points. What we are saying here is that there is enough information in the minimums to determine the rest and the argument raised is sufficient as the basis for the evidence.

With all the indicators on green, it is time to get back to something else.

## 5.Back to the theorems and proofs.

### 5.1 Continuity of R2(a,b).

## Theorem 9

The $R 2(a, b)$ function is continuous in interval $0 \leq a \leq 1 / 2$.

## Proof

It suffices to prove that the $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$, i.e. its denominator $\mathrm{SC} 1(\mathrm{a}, \mathrm{b})=(\mathrm{C} 1(\mathrm{a}, \mathrm{b}))^{2}+(\mathrm{S} 1(\mathrm{a}, \mathrm{b}))^{2}$ does not cancel. This is theorem 7.

Let us note that the function is also continuous outside the indicated interval.

### 5.2 Calculation of the partial derivative linked to R2(a,b).

## Writing convention.

In this text, the functions are generally dependent on two variables $a$ and $b$. The handling of the objects is simplified by writing $F$ instead of $F(a, b)$. The partial derivative of $F$, versus parameter $a, \partial / \partial a(F(a, b))$ is simplified in $\partial_{a} F$. The same goes for $b$. In the text body, we defined the functions $\operatorname{Ck}(a, b)$ and $S_{k}(a, b)$. The non-recalled entries of parameters $a$ and $b$ are equivalent as well as the indexing $\mathrm{k}: \operatorname{Ck}(\mathrm{a}, \mathrm{b})=\mathrm{C}_{\mathrm{k}}(\mathrm{a}, \mathrm{b})=\mathrm{Ck}=\mathrm{C}_{\mathrm{k}}$ and $\operatorname{Sk}(\mathrm{a}, \mathrm{b})=\mathrm{S}_{\mathrm{k}}(\mathrm{a}, \mathrm{b})=\mathrm{Sk}=\mathrm{S}_{\mathrm{k}}$.

Evaluation of the partial derivatives of $\mathrm{Ck}(\mathrm{a}, \mathrm{b})$ and $\mathrm{Sk}(\mathrm{a}, \mathrm{b})$.
From relations (14) and (15), we get :
and

$$
\mathrm{Ck}=\sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}-1+\mathrm{k}} \cdot(\operatorname{Ln}(\mathrm{~m}))^{\mathrm{k}} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \cos (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m}))
$$

$$
\mathrm{Sk}=\sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}-1+\mathrm{k}} \cdot(\operatorname{Ln}(\mathrm{~m}))^{\mathrm{k}} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \sin (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m}))
$$

We deduct immediately

$$
\begin{aligned}
& \partial_{\mathrm{a}} \mathrm{Ck}= \sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}+\mathrm{k}} \cdot(\operatorname{Ln}(\mathrm{~m}))^{\mathrm{k}+1} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \cos (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m})) \\
& \\
& \partial_{\mathrm{a}} \mathrm{Sk}= \sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}+\mathrm{k}} \cdot(\operatorname{Ln}(\mathrm{~m}))^{\mathrm{k}+1} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \sin (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m})) \\
& \\
& \partial_{\mathrm{b}} \mathrm{Ck}=\sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}+\mathrm{k}} \cdot(\operatorname{Ln}(\mathrm{~m}))^{\mathrm{k}+1} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \sin (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m}))
\end{aligned}
$$

and

$$
\partial_{\mathrm{b}} \mathrm{Sk}=\sum_{\mathrm{m}=1}^{\infty}(-1)^{\mathrm{m}-1+\mathrm{k}} \cdot(\operatorname{Ln}(\mathrm{~m}))^{\mathrm{k}+1} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \cos (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m}))
$$

In other words :

$$
\begin{align*}
& \partial_{\mathrm{a}} \mathrm{Ck}=\mathrm{C}_{\mathrm{k}+1} \\
& \partial_{\mathrm{a}} \mathrm{Sk}=\mathrm{S}_{\mathrm{k}+1}  \tag{29}\\
& \partial_{\mathrm{b}} \mathrm{Ck}=\mathrm{S}_{\mathrm{k}+1} \\
& \partial_{\mathrm{b}} \mathrm{Sk}=(-1) \cdot \mathrm{C}_{\mathrm{k}+1}
\end{align*}
$$

All of this functions, as sums (finite or infinite) of continuous functions are continuous.

From relation (18), we get :

$$
\mathrm{R} 2=\frac{\mathrm{C} 0 . \mathrm{C} 2+\mathrm{S} 0 . \mathrm{S} 2}{\mathrm{C} 1^{2}+\mathrm{S} 1^{2}}
$$

It follows using identity $(u / v)^{\prime}=\left(u^{\prime} . v-u . v^{\prime}\right) / v^{2}$ :

$$
\begin{align*}
& \partial_{\mathrm{a}} \mathrm{R} 2=\frac{\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}+2 \mathrm{C} 0 \cdot \mathrm{C} 2+2 \mathrm{~S} 0 \cdot \mathrm{~S} 2\right) \cdot(\mathrm{C} 1 \cdot \mathrm{C} 2+\mathrm{S} 1 \cdot \mathrm{~S} 2)+\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}\right) \cdot(\mathrm{C} 0 \cdot \mathrm{C} 3+\mathrm{S} 0 \cdot \mathrm{~S} 3)}{\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}\right)^{2}}  \tag{30}\\
& \partial_{\mathrm{b}} \mathrm{R} 2=\frac{\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}+2 \mathrm{C} 0 \cdot \mathrm{C} 2+2 \mathrm{~S} 0 \cdot \mathrm{~S} 2\right) \cdot(\mathrm{C} 1 \cdot \mathrm{~S} 2-\mathrm{S} 1 \cdot \mathrm{C} 2)+\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}\right) \cdot(\mathrm{S} 0 \cdot \mathrm{C} 3-\mathrm{C} 0 \cdot \mathrm{~S} 3)}{\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}\right)^{2}} \tag{31}
\end{align*}
$$

Note:
The two previous partial derivatives are continuous due to the fact that $(\mathrm{Cl}(\mathrm{a}, \mathrm{b}))^{2}+(\mathrm{S} 1(\mathrm{a}, \mathrm{b}))^{2}$ doesn't cancel (see again theorems 7 and 9).

### 5.3 The impossibility of $\mathbf{R 2}(\mathbf{a}, \mathrm{b})=\mathbf{- 1}$.

When we talk about the impossibility of $\mathrm{R} 2=-1$, we mean at the same time the impossibility of $\mathrm{R} 2<-1$ since $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ is continuous according to both coordinates $a$ and $b$. In addition, we place ourselves in the conditions $a \in[0,1 / 2]$ and $b \in$ $[3,+\infty[$.

## Framework of the proof

From relation (18), we get by definition $\mathrm{R} 2=(\mathrm{C} 0 . \mathrm{C} 2+\mathrm{S} 0 . \mathrm{S} 2) /\left(\mathrm{C}^{2}+\mathrm{S} 1^{2}\right)$, so that also $(\mathrm{C} 0 . \mathrm{C} 2+\mathrm{S} 0 . \mathrm{S} 2)=\mathrm{R} 2 .\left(\mathrm{C}^{2}+\mathrm{S} 1^{2}\right)$. Relation (31) becomes then :

$$
\begin{equation*}
\partial_{\mathrm{b}} \mathrm{R} 2=\frac{(1+2 \mathrm{R} 2) \cdot(\mathrm{C} 1 \cdot \mathrm{~S} 2-\mathrm{S} 1 \cdot \mathrm{C} 2)+(\mathrm{S} 0 \cdot \mathrm{C} 3-\mathrm{C} 0 \cdot \mathrm{~S} 3)}{\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}\right)} \tag{32}
\end{equation*}
$$

We seek the values for which the R 2 expression is minimal when b varies, thus those such that $\partial_{\mathrm{b}} \mathrm{R} 2=0$, meaning also R2 = (1/2).((S0.C3-C0.S3)/(C1.S2-S1.C2)-1). The solutions are hence those for which we have simultaneously :

$$
\begin{equation*}
\mathrm{R} 2 \mathrm{x}=\frac{\mathrm{C} 0 . \mathrm{C} 2+\mathrm{S} 0 . \mathrm{S} 2}{\mathrm{C} 1^{2}+\mathrm{S} 1^{2}} \tag{33}
\end{equation*}
$$

and

$$
\begin{equation*}
R 2 y=(1 / 2) \cdot\left(\frac{\mathrm{C} 0 . \mathrm{S} 3-\mathrm{C} 3 \cdot \mathrm{~S} 0}{\mathrm{C} 1 . \mathrm{S} 2-\mathrm{C} 2 \cdot \mathrm{~S} 1}-1\right) \tag{34}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathrm{R} 2=\mathrm{R} 2 \mathrm{x}=\mathrm{R} 2 \mathrm{y} \tag{35}
\end{equation*}
$$

The two graphics below are the same, the second being a close-up view of a particular area. They contain all the ( $\mathrm{R} 2 \mathrm{x}(\mathrm{a}, \mathrm{b}$ ), $\mathrm{R} 2 \mathrm{y}(\mathrm{a}, \mathrm{b})$ ) points obtained for a $1 / 2, \mathrm{~b}=0$ to 20000 and $\Delta \mathrm{b}=1 / 4$, the actual solutions joining these points by continuity. The point $(R 2 x, R 2 y) \approx(-0.5122,-0.5121)$ for $(a, b)=(1 / 2,78974.87502)$ corresponding to the only example found where $R 2(a, b)<-1 / 2$ is also reported on the graphic. The only solutions to retain are on the $R 2 x=R 2 y$ axis of this graphic (the light blue dotted line), but the usefulness of spotting all the dots ( $R 2 x, R 2 y$ ) is obvious. This makes it possible to visualize in an obvious or even garish way, the minimum abscissa when simultaneous equalities are obtained. We see that the dots are concentrated, for the part below the abscissa $R 2 x=0$, in a triangle $R 2 y=-1 / 2, R 2 x=0, R 2 y=1 / 2+2 . R 2 x$ (green frame). The low point of this triangle is $-1 / 2$. A few points are slightly outside this triangle, but this does not affect our conclusion. One finds them mostly above the triangle near the $0^{-}$abscissa.

Such a figure with very sharp boundary lines, although slightly permeable, show the absurdity of points extending far beyond $R 2 x<-1 / 2$, namely to a hypothetical $R 2 x=-1$, for $a=1 / 2$, complementary information being given for $a \in[0,1]$ in Appendix 10

The first graph above shows a concentration of coordinates ( $R x, R y$ ) along and below the axis $R y=-1 / 2$ when $R x$ tends towards infinity. However, the effective solutions are those placed on the axis Rx = Ry. This means the scarcity of high peak values both because of the scarcity of points along the axis $\mathrm{Ry}=-1 / 2$ and the distance of the line $\mathrm{Rx}=\mathrm{Ry}$ from the said line. Therefore a double penalty in some way...

A framework that is a little closer to reality can be given by reparametrizing the initial line $R 2 y=1 / 2+2 R 2 x$ (upper line in green underneath) into a new form $R 2 y=1 / 2+2 R 2 x+(1 / 12) \cdot \tan (\pi \cdot(R 2 x+1 / 2))$, which does not change in any way the hereby argument.

The slope of the curve giving R2y as a function of $R 2 x$ is $\infty$ on the dotted blue line $R 2 y=R 2 x$ as shown in the example below and those of appendix 11. This follows from the construction of this graph which initially uses the relationship $\partial_{b} R 2$ $=0$ (see page 18) and therefore results in $\partial \mathrm{bR} 2 \mathrm{x}=0$ precisely on the line $R 2 \mathrm{x}=\mathrm{R} 2 \mathrm{y}$.

This slope is also infinite for the divergences of R2y, that is to say when C1.S2-C2.S1 $=0$ but then there is of course no corresponding point on the curve itself (see again appendix 11).

The previous graphics thus show that points cannot reach the -1 abscissa (remaining the fact that overruns of $-1 / 2$ are possible).

The population density of points such that $|R 2 x-R 2 y|<s$, s some given threshold, is relatively constant regardless of intervals b such as [10000k, 10000. $(\mathrm{k}+1)[, \mathrm{k}=0$ to 19 , chosen from our data collecting. This is the subject of the graphic (39).

Graphic 40 shows the population density relative to the R 2 x parameter for intervals like $[0.1 \mathrm{k}, 0.1(\mathrm{k}+1)[, \mathrm{k}-10$ to 25 , crossed with the criterion $|\mathrm{R} 2 \mathrm{x}-\mathrm{R} 2 \mathrm{y}|<\mathrm{s}$. Points' population peaks are centred on $\mathrm{R} 2 \mathrm{x} \in[-0.1,0]$ and $\mathrm{R} 2 \mathrm{x} \in[1,1.1]$ intervals and collapse very rapidly on each side of the first peak instance.

## Theorem 10

The minimal value of $R 2(a, b)$ is -1 excluded.

## Proof

From relations (18) and (32), because $\partial_{\mathrm{b}} \mathrm{R} 2=0$, we get the two following equations to be solved :

$$
\begin{gathered}
(\mathrm{C} 2) \cdot \mathrm{C} 0+(\mathrm{S} 2) \cdot \mathrm{S} 0-\mathrm{R} 2 \cdot\left(\mathrm{C}^{2}+\mathrm{S} 1^{2}\right)=0 \\
(\mathrm{~S} 3) \cdot \mathrm{C} 0-(\mathrm{C} 3) \cdot \mathrm{S} 0-(1+2 \mathrm{R} 2) \cdot(\mathrm{C} 1 \cdot \mathrm{~S} 2-\mathrm{S} 1 \cdot \mathrm{C} 2)=0
\end{gathered}
$$

So that :

$$
\binom{\mathrm{C} 0}{\mathrm{~S} 0}=\left(\begin{array}{cc}
\mathrm{C} 2 & \mathrm{~S} 2 \\
\mathrm{~S} 3 & -\mathrm{C} 3
\end{array}\right)^{-1}\binom{\mathrm{R} 2 .\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}\right)}{(1+2 \mathrm{R} 2) \cdot(\mathrm{C} 1 . \mathrm{S} 2-\mathrm{S} 1 . \mathrm{C} 2)}
$$

Then

$$
\binom{\mathrm{C} 0}{\mathrm{~S} 0}=\left(\frac{1}{\mathrm{C} 2 . \mathrm{C} 3+\mathrm{S} 2 . \mathrm{S} 3}\right) \cdot\left(\begin{array}{cc}
\mathrm{C} 3 & \mathrm{~S} 2 \\
\mathrm{~S} 3 & -\mathrm{C} 2
\end{array}\right)\binom{\mathrm{R} 2 \cdot\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}\right)}{(1+2 \mathrm{R} 2) \cdot(\mathrm{C} 1 . \mathrm{S} 2-\mathrm{S} 1 . \mathrm{C} 2)}
$$

Let us write

$$
\begin{gathered}
\alpha=\mathrm{R} 2 .\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}\right) \\
\beta=(1+2 \mathrm{R} 2) .(\mathrm{C} 1 . \mathrm{S} 2-\mathrm{S} 1 . \mathrm{C} 2)
\end{gathered}
$$

Then :

$$
\mathrm{C}^{2}+\mathrm{S} 0^{2}=\frac{\alpha^{2} \cdot\left(\mathrm{C}^{2}+\mathrm{S} 3^{2}\right)+\beta^{2} \cdot\left(\mathrm{C} 2^{2}+\mathrm{S} 2^{2}\right)+2 \alpha \cdot \beta \cdot(\mathrm{C} 3 \cdot \mathrm{~S} 2-\mathrm{C} 2 \cdot \mathrm{~S} 3)}{(\mathrm{C} 2 \cdot \mathrm{C} 3+\mathrm{S} 2 \cdot \mathrm{~S} 3)^{2}}
$$

Let us write the ratio :

$$
\begin{equation*}
\operatorname{DSC}(\ldots)=\frac{\alpha^{2} \cdot\left(\mathrm{C}^{2}+\mathrm{S} 3^{2}\right)+\beta^{2} \cdot\left(\mathrm{C} 2^{2}+\mathrm{S} 2^{2}\right)+2 \alpha \cdot \beta \cdot(\mathrm{C} 3 \cdot \mathrm{~S} 2-\mathrm{C} 2 \cdot \mathrm{~S} 3)}{(\mathrm{C} 2 \cdot \mathrm{C} 3+\mathrm{S} 2 \cdot \mathrm{~S} 3)^{2} \cdot\left(\mathrm{C} 0^{2}+\mathrm{S} 0^{2}\right)} \tag{36}
\end{equation*}
$$

and

$$
\operatorname{DL}(\ldots)=\operatorname{Ln}(\operatorname{DSC}(\ldots))
$$

A good understanding of the argument requires, as before, the distinction between the two cases $\mathrm{R} 2(\mathrm{a}, \mathrm{b})=-1 / 2$ and $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ $=-1$, knowing that continuity gives perfectly accessible intermediate values, if necessary, between these two cases.

If R2 $=-1 / 2$, we write $\operatorname{DSC} 0=\operatorname{DSC}(-1 / 2)$, expression DSC being defined above, so that also :

$$
\mathrm{DSC} 0=\frac{\left(\mathrm{C}^{2}+\mathrm{S} 1^{2}\right)^{2} \cdot\left(\mathrm{C} 3^{2}+\mathrm{S}^{2}\right)}{4 \cdot\left(\mathrm{C} 0^{2}+\mathrm{S} 0^{2}\right) \cdot(\mathrm{C} 2 \cdot \mathrm{C} 3+\mathrm{S} 2 \cdot \mathrm{~S} 3)^{2}}
$$

and

$$
\mathrm{DL} 0=\operatorname{Ln}(\mathrm{DSC} 0)
$$

The $R(a, b)=-1 / 2$ is reached when

$$
\mathrm{DSC} 0=1
$$

or as well

$$
\text { DL0 }=0
$$

If $R(a, b)=-1$, we write $\operatorname{DSC} 1=\operatorname{DSC}(-1)$, so that :

$$
\mathrm{DSC} 1=\frac{\left(\mathrm{C} 2^{2}+\mathrm{S} 2^{2}\right) \cdot(\mathrm{C} 1 \cdot \mathrm{~S} 2-\mathrm{C} 2 \cdot \mathrm{~S} 1)^{2}+\left(\mathrm{C}^{2}+\mathrm{S}^{2}\right) \cdot\left(\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}\right) \cdot\left(\mathrm{C} 3^{2}+\mathrm{S} 3^{2}\right)+2 \cdot(\mathrm{C} 1 \cdot \mathrm{~S} 2-\mathrm{C} 2 \cdot \mathrm{~S} 1)(\mathrm{C} 3 \cdot \mathrm{~S} 2-\mathrm{C} 2 \cdot \mathrm{~S} 3)\right)}{\left(\mathrm{C} 0^{2}+\mathrm{S} 0^{2}\right) \cdot(\mathrm{C} 2 \cdot \mathrm{C} 3+\mathrm{S} 2 \cdot \mathrm{~S} 3)^{2}}
$$

and

$$
\mathrm{DL} 1=\operatorname{Ln}(\mathrm{DSC} 1)
$$

The $R(a, b)=-1$ case is reached when

$$
\begin{gathered}
\mathrm{DSC} 1=1 \\
\mathrm{DL} 1=0
\end{gathered}
$$

or else

Graphics of DSC0 and DSC1 below are, in fact, point clouds' variants undergoing a continuous distortion of the graphics obtained in the first part of this demonstration. They show the same thing in a slightly different form.

The first graphic (graphic41) shows the outgrowth of the minimums, on the negative R 2 side, aligned on the line $\operatorname{Ln}(\mathrm{DSC} 0$ ) $=0$. For the second graphic (graphic 42), the outgrowth is deflected upwards showing the impossibility of reaching $\mathrm{R} 2=$ -1 values. On line $\operatorname{Ln}(\mathrm{DSC} 1)=0$, where this event $\mathrm{R} 2=-1$ must be effective to reject Riemann's hypothesis, the intersection is not only above $-1 / 2$, but much further beyond $0^{+}$.

Finally, let us look at the precise reason why $\mathrm{R} 2(\mathrm{a}, \mathrm{b})=-1$ events are not achieved by local punctual examples. For this, we choose the case for which we detected the smallest difference between Riemann's zeroes among the first 500000 of them and a few others.

The graphic below shows simultaneously, one on one, the evolution of R 2 and $\operatorname{Ln}(\mathrm{DSCl})$. We recall that $\operatorname{Ln}(\mathrm{DSC} 1)=0$ (or $\mathrm{DSC} 1=1$ ) is the target value right above the R 2 minimums.

The initiation of an R 2 descent induces the initiation of a $\operatorname{Ln}(\mathrm{DSC} 1)$ ascent and vice versa as shows the examples below. This behaviour is perfectly reproducible, as shown by the two graphics that follow.

The crossing of R 2 and $\operatorname{Ln}(\mathrm{DSC} 1)$ curves at the approach of a low-R2 zone is at the level of ordinate 0 and $\operatorname{Ln}(\mathrm{DSC} 1)$ then quickly increases.
Let us consider the intersections of the R 2 and $\operatorname{Ln}(\mathrm{DSC} 1)$ curves. We call inner crossings those whose abscissas are between two Riemann's zeros and outer crossings the other two to the right and left (of graphic 45). The term $\operatorname{Ln}(\mathrm{DSC} 1)$ necessarily diverges according to the relationship 36 since $\mathrm{C}^{2}+\mathrm{S}^{2}=0$ for any Riemann (and Dirichlet) zero. So, the inner crossings are trivially above ordinate 0 . The outer crossings are also, a point that however seems difficult to establish. The easiest way is to assess the value of DSC1 at the points that matter to us, that is where R 2 is minimum.

For this, we pick the data used to establish graphic 29 with the same selection criterion chosen at that time. The corresponding table is in Appendix 6 Table 10. Doing so, we get the graphics below (the second graph being a zoom of the first on the area of low values of $\Delta \mathrm{br}$ the gaps between Riemann zeros) :

We recorded DSC1- the value of DSC1 for the $\mathrm{r}_{\mathrm{M}}$ - abscissa before the peak and DSC1+ the value for the $\mathrm{r}_{\mathrm{M}}+$ abscissa after the peak. We have also reported in the graphics the average DSC1 value of these two values, knowing that what really is important here is rather the minimum value of the two values DSC1- and DSC1+.

The alignment of the points fails (which then offers no useful information) for a gap between zeroes of Riemann higher than approximatively $\Delta b_{r}=1 / 2$ in exactly the same way we had found in the case of graphic 29 .

However, the points interesting us, i.e. cases where the R 2 ratio is likely to be close to the -1 value, are necessarily points sticking to the origin of the abscissas (extremely small $\Delta \mathrm{br}$ ). This area corresponds to the uprise of DSC1 well beyond the critical value $\mathrm{DSC1}=1$. This upswing is due to the simple fact that the closer two Riemann zeros are, the more pronounced the corresponding peak is and the steeper the flanks of the peak, including until the abscissas of the minimums of R2. Thus, the abscissa of a minimum ( rM - or $\mathrm{rM}+$ ) of R 2 is close to that of its corresponding zero, in other words, when $\Delta \mathrm{br}$ $\rightarrow 0$, then $\mathrm{C} 0^{2}+\mathrm{S}^{2} \rightarrow 0$ at the abscissas rM - and $\mathrm{rM}+$ also. But $\mathrm{C} 0^{2}+\mathrm{S} 0^{2} \rightarrow 0$ is at the DSC1 denominator and no term in C 0 or S 0 is within the numerator for compensation. The term $\mathrm{C}^{2}+\mathrm{S}^{2}$, and even more $\mathrm{C}^{2}+\mathrm{S}^{2}$, will tend to 0 with many decades of delay as shown by the typical example of graphic 5 , the number of decades increasing rapidly with the lowering of $\Delta$ br. The other terms do not tend in any way towards 0 . The compensation remains effective in DSC0 because of the square of $\mathrm{C} 1^{2}+\mathrm{S} 1^{2}$ in the DSC 0 numerator, but it would take a power of at least 4 effected to $\mathrm{C}^{2}+\mathrm{S} 2^{2}$ in DSC 1 (plus 3 very close zeros at least) to obtain the said compensation. Thus, DSC1 necessarily diverges when $\Delta \mathrm{br} \rightarrow 0$ and so in a very steep manner.

We extended the study to the intermediate value of $\mathrm{R} 2 \mathrm{y}=-0.5$ to -1 by $1 / 10$ steps. Appendix 6 Table 11 gives the values corresponding to the underneath graphic. For R2y $=-0.5$, we collected points below $\operatorname{DSC}(X)=1$ which is of course expected and thus authorizes the existence of $\mathrm{R} 2(\mathrm{a}, \mathrm{b})<-0.5$, of which we found a unique example (see appendix 5). The calibration thanks to the graphic below shows, at the same time, that the limit value is close to it. The existence of points such as $\mathrm{R} 2(\mathrm{a}, \mathrm{b})<-0.6$ without being totally unthinkable (because the points represented here are only the image of a larger dot cloud if one uses more data) is certainly a quite rare event.

The rise of the points obtained for the DSC1 expression near the origin $\left(\Delta \mathrm{b}_{\mathrm{r}}<\approx 0.15\right)$ and their alignment besides that ( $\Delta \mathrm{b}_{\mathrm{r}}$ $<\approx 0.35$ ) is independent of the abscissas of the Riemann's zeroes (is dependent only on the gap between the said zeroes) completing this proof.

## Note:

The reader will note that all the examples of this proof are built with $\mathrm{a}=1 / 2$. Indeed, the peak values are (for the part of the critical band $\mathrm{a} \leq 1 / 2$ ) on the critical line. The presentation of the numerical results is interesting only for this critical line, as the values of the extremums decline otherwise very quickly (for $\mathrm{a}<1 / 2$ ) not allowing to find additional solutions that can contradict our presentation in a relevant way.

## Theorem 11

The asymptotic value of the $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ minimums is $-1 / 2$.

## Proof

By the term "asymptotic," we mean the minimums of $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ when b tends towards infinity (and the parameter a is fixed). In this case, Riemann's zeros are, on average, at a distance of about $2 \pi / \mathrm{Ln}(\mathrm{br})$, meaning nearer and nearer. According to the relation (31), the numerator of $\partial_{\mathrm{b}} \mathrm{R} 2$ is equal to $\left(\mathrm{C}^{2}+\mathrm{S} 1^{2}+2 \mathrm{C} 0 . \mathrm{C} 2+2 \mathrm{~S} 0 . \mathrm{S} 2\right) .(\mathrm{C} 1 . \mathrm{S} 2-\mathrm{S} 1 . \mathrm{C} 2)+\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}\right) \cdot(\mathrm{S} 0 . \mathrm{C} 3-\mathrm{C} 0 . \mathrm{S} 3)$. The cancellation of $\partial_{b} \mathrm{R} 2$ occurs for $(\mathrm{C} 0 . \mathrm{C} 2+\mathrm{S} 0 . \mathrm{S} 2) /\left(\mathrm{C}^{2}+\mathrm{S} 1^{2}\right)=(1 / 2) .((\mathrm{C} 0 . \mathrm{S} 3-\mathrm{S} 0 . \mathrm{C} 3) /(\mathrm{C} 1 . \mathrm{S} 2-\mathrm{S} 1 . \mathrm{C} 2)-1)$, in other words when :

$$
\begin{equation*}
\mathrm{R} 2=\frac{-1}{2}+\frac{\mathrm{C} 0 \cdot \mathrm{~S} 3-\mathrm{S} 0 \cdot \mathrm{C} 3}{2 \cdot(\mathrm{C} 1 \cdot \mathrm{~S} 2-\mathrm{S} 1 \cdot \mathrm{C} 2)} \tag{37}
\end{equation*}
$$

Asymptotically, as we saw in the last part of the proof of the impossibility of R2 = -1, the terms C0 and S0 tend towards 0 much faster than all the terms of the Ck and Sk's type, $\mathrm{k}>0$. It immediately follows $\mathrm{R} 2 \rightarrow-1 / 2$.

## Note 1:

This result reminds us that negative overruns of -0.5 are possible. These will become more frequent when bincreases. But, asymptotically, these overruns will also be more and more restricted to the immediate vicinity of -0.5 and therefore without the possibility of joining -1 , thus confirming again theorem 10 .

## Note 2:

At the peak abscissa $r_{\text {peak }}$, the expression C1.S2-S1.C2 necessarily takes values very close to 0 , taking away this prerogative from the other two extremums (the minimums).

## Numerical examples.

The examples below are realized thanks to the online computer application Pari gp using the computer program given in appendix 9

These are the three cases with smallest gaps between Riemann's zeros of abscissas less than $b=2000000$. We actually systematically obtain values close to -0.5 (between -0.48 and -0.51 ).

The "theoretical" value of the peak (truncation $+\infty$ ) is obtained from the formula $r_{\text {peak }} \approx 1+5 /\left(\Delta b_{r}{ }^{2} \cdot b_{r}{ }^{1 / 4}\right)$. It is difficult to obtain the actual precis value of these peaks numerically (see again appendix 9). Some values concerning the minimums $\mathrm{r}_{\mathrm{M}}$ - and $\mathrm{r}_{\mathrm{M}+}$ of R2 to the left and right of the Riemann's zeros surrounding a peak also remain imprecise if the truncation does not include enough terms.
The reader will be able to compare the final truncations used to the numbers of terms $\mathrm{m} \approx 1 /(\exp (\pi / \mathrm{b})-1)$ corresponding to the last jump of values of the terms $\sum(-1)^{\mathrm{m}+\mathrm{k}} \cdot(\operatorname{Ln}(\mathrm{m}))^{\mathrm{k}+1} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \cos (\mathrm{b} \cdot \operatorname{Ln}(\mathrm{m}))$ and $\sum(-1)^{\mathrm{m}+\mathrm{k}} \cdot(\operatorname{Ln}(\mathrm{m}))^{\mathrm{k}+1} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \sin (\mathrm{b} \cdot \operatorname{Ln}(\mathrm{m}))$. For more information, refer to Appendix 1 relationship 38.

### 5.4 The exception to the rule.

We found an exception to the minimum rule of -1 very early in this text (see note of theorem 4). It is essential to give the reason for it because, although of no practical importance as it is local and therefore of easily verifiable effect, it is nevertheless like a thorn in the foot from the theoretical point of view.

The very particular case b < br1
We examine the case where abscissa $b$ is lower than that of the first Riemann zero and its development out from this area. The types of curves and choice of colours are the same as before. In particular, the dark blue curve represents the points (R2x, R2y).

The reader can see that as soon as the blue curve crosses abscissa $\mathrm{R} 2 \mathrm{x}=0$, it is trapped in the areas described above despite all the restlessness, to say the least, that reigns there.

Why can R 2 x be less than -1 for small values of b ?
Some rule will apply in a context and only in this case. It is not otherwise here.
Indeed, we note the evolutions of the values of $\cos (\mathrm{b} \cdot \ln (\mathrm{m}))$ and $\sin (\mathrm{b} \cdot \ln (\mathrm{m}))$, in the sums Ck and Sk as a function of m , for truncation $\mathrm{m}=1$ to 10000 and two values of b , as examples below :

Let us take these values for two additional cases, with further examples provided in Appendix 12. Let us list the values of these two expressions (intimately linked by the sum of their squares). Then let us list them by increasing values. We get the graphs below. We observe that the distribution is not according to a fixed scheme for small values of $b$. It gradually tends however, as bincreases, towards a unique sinusoidal distribution common to the elements of $\sum \cos (\mathrm{b} \cdot \ln (\mathrm{m}))$ and those of $\sum \sin (\mathrm{b} \cdot \ln (\mathrm{m}))$. The minimum -1 rule is necessarily subject to a certain strict framework. We note that this frame is the existence of this sinusoidal distribution. Thus, the deviation from the minimum rule can be acceptable up to the
somewhat very approximate value $\mathrm{b} \approx \mathrm{br} 1(\approx 14)$. Beyond this region, a type distribution $\cos \left(\pi \cdot\left(\mathrm{m} / \mathrm{m}_{\max }+1\right)\right)$ settles permanently and will remain unique up to $b$ infinite. Of course, truncation cannot be limited to $\mathrm{m}_{\max }=10000$ terms when b increases.

Of course also, except for $\mathrm{b}=0$, by taking a truncation with more terms (than 10000), we can find a sinusoidal profile for small values of $b$. But this takes place while the additional terms have only a negligible effect on the asymptotic value of R2x, the latter being essentially built on the first terms. The profile of the distribution must be "complete" in the useful truncation zone, where it has a real effect on the value of R 2 x (that is R 2 ), otherwise it is strictly speaking effectively "incomplete".

## Is the unique asymptotic distribution sufficient to impose R 2 x greater than -1 for $\mathrm{b}>\mathrm{br} 1$ ?

In other words, how many b-values need to be checked before concluding that the minimum value cited is legitimate each time (and that we are in the presence of a theorem) ?

Well, to whom will object that this is only a few calculations on a tiny part of the values that can take $b$, we recall that the b-parameter is encapsulated in the cosine and sinus functions that can only take values between -1 to 1 . The neighbourhoods of all values within this interval are reached thousands of times (for $\mathrm{b}<20000$ for example) and the functions are continuous. Of course, not all possibilities are covered, but the sample is quite representative of the whole system of equations. In addition, if the examples are necessarily specific, the relationships and thus conclusions are general.

Note: We do not say, however, that giving random values to $\cos (\mathrm{b} \cdot \ln (\mathrm{m})$ ) between -1 and 1 (with corresponding values deduced for $\sin (\mathrm{b} \cdot \ln (\mathrm{m}))$ ) would give results for R 2 greater than -1 because this is in fact not the case. It is necessary to have $(\cos (b \cdot \ln (\mathrm{~m})), \sin (\mathrm{b} \cdot \ln (\mathrm{m})))$ and $\mathrm{m}=0,1,2$, etc. in this order in the equations for everything to work according to the expectation.

## 6.Conclusion.

We studied a convexity condition to confirm Riemann's hypothesis. This condition is a sufficient condition, meaning a violation, apart from that of the one already cited, would not necessarily deny the hypothesis. The way the proof was implemented makes it possible to calibrate the "distance" to a possible denial and shows a much to wide gap to this possibility. Several formulas, such as relationships (23), (24), (27), (36), (44) have been established implying geometric
parameters links that impose the existence of the sole critical line for Riemann zeroes without any point departing from it. We used an approximate truncation method for assessing these parameters, with appendix 1 legitimizing it. It would be interesting, however, to find an alternative method similar to that used for the evaluation of Riemann's zeroes to determine the relationships, or points clouds, both much faster and with greater precision (see provision made in Appendix 9). The particular shape of the curves in graphic 14, the set of parameters leading to it and the relationship between them also deserve extra attention.

This done and said, in a thousand years, when another eminent reader, that the one who reads us here, will wake up, his wish will be all the more satisfied. If not, we will tell him : "Young man", in mathematics, you don't understand things, you get used to them". John Von Neumann.

## Appendix 1 : Truncation. Precision of evaluations.

The numerical evaluations within of the body of text are drawn from expressions with infinite numbers of terms. They are based on approximations by truncation at a certain rank n. Expressions are the combinations of

$$
\mathrm{Ck}(\mathrm{a}, \mathrm{~b})=\operatorname{Lim}_{\mathrm{n} \rightarrow+\infty} \sum_{\mathrm{m}=1}^{\mathrm{n}}(-1)^{\mathrm{m}-1+\mathrm{k}} \cdot(\operatorname{Ln}(\mathrm{~m}))^{\mathrm{k}} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \cos (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m}))
$$

and

$$
\operatorname{Sk}(\mathrm{a}, \mathrm{~b})=\operatorname{Lim}_{\mathrm{n} \rightarrow+\infty} \sum_{\mathrm{m}=1}^{\mathrm{n}}(-1)^{\mathrm{m}-1+\mathrm{k}} \cdot(\operatorname{Ln}(\mathrm{~m}))^{\mathrm{k}} \cdot \mathrm{~m}^{-\mathrm{a}} \cdot \sin (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m}))
$$

which shapes as a function of n is typically the followings :

The particular look of these graphics can give the reader the impression that it is impossible to assess the value of expression to infinity. Indeed, leaps in values appear at abscissas that may seem random. What guarantee do we have here that a new jump will not arise somewhere asymptotically? To find out what is happening, it is necessary to trace the origin of these jumps. The sums we are talking about here are alternating sums. A jump comes from the fact that a given term is followed by a term of the same sign and this "many" times. So let us consider what produces the sign of two terms that follow each other. Within $(-1)^{\mathrm{m}-1+\mathrm{t}} \cdot(\operatorname{Ln}(\mathrm{m}))^{\mathrm{k}} \cdot \mathrm{m}^{-\mathrm{a}} \cdot \cos (\mathrm{b} \cdot \operatorname{Ln}(\mathrm{m}))$, neither $\operatorname{Ln}(\mathrm{m})$ in general nor $\mathrm{m}^{-\mathrm{a}}$ have any effect on the change of sign. It remains therefore $(-1)^{\mathrm{m}} \cdot \cos (\mathrm{b} \cdot \operatorname{Ln}(\mathrm{m}))$, k being a constant term that can be eliminated. For two successive terms to be the same sign, it is sufficient asymptotically that $(-1)^{\mathrm{m}} \cdot \cos (\mathrm{b} \cdot \operatorname{Ln}(\mathrm{m})) \approx(-1)^{\mathrm{m}+1} \cdot \cos (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m}+1))$ since $\operatorname{Ln}(\mathrm{m})$ and $\operatorname{Ln}(m+1)$ are of close values. From that, we deduce $\cos (b \cdot \operatorname{Ln}(m+1)) \approx-\cos (b \cdot \operatorname{Ln}(m))$, or $\cos (b \cdot \operatorname{Ln}(m+1)) \approx \cos (\pi+b \cdot \operatorname{Ln}(m))$, and then $\mathrm{b} \cdot \operatorname{Ln}(\mathrm{m}+1) \approx(1+2 \mathrm{k}) \cdot \pi+\mathrm{b} \cdot \operatorname{Ln}(\mathrm{m})$, or finally :

$$
\mathrm{b} \cdot \operatorname{Ln}(1+1 / \mathrm{m})) / \pi \approx 1+2 \mathrm{k}
$$

where $\mathrm{k} \in \mathrm{Z}$.
For $\mathrm{b}>0$ and $\mathrm{m}>0, \mathrm{k}$ is necessarily in N .
When $\mathrm{m} \rightarrow+\infty$, and b has some given value, the product $\mathrm{b} \cdot \operatorname{Ln}(1+1 / \mathrm{m})) / \pi \rightarrow 0$, so that the values of m for which b. $\operatorname{Ln}(1+1 / \mathrm{m})) / \pi \approx 1$ are the last ones for which a jump occurs. The initial expression will converge after this last leap which intervenes at abscissa :

$$
\begin{equation*}
\mathrm{m} \approx 1 /(\exp (\pi / b)-1) \tag{38}
\end{equation*}
$$

In the case of the graphics 62 to 64 examples, $\mathrm{m} \approx 1 /(\exp (\pi / 15300)-1) \approx 4870$.
The other jumps occur around $m$ abscissas such as :

$$
\mathrm{m} \approx 1 /(\exp ((1+2 \mathrm{k}) \cdot \pi / \mathrm{b})-1)
$$

That is for hereby example

## Table 3

| k | m |
| :---: | :---: |
| $\ldots$ | $\ldots$ |
| 10 | 231 |
| 9 | 256 |
| 8 | 286 |
| 7 | 324 |
| 6 | 374 |
| 5 | 442 |
| 4 | 541 |
| 3 | 695 |
| 2 | 974 |
| 1 | 1623 |
| 0 | 4869 |

This table explains the "chaos" near the origin of the abscissas.
The so found expression also allows to give approximately the rank $n$ sufficient, versus some $b$, to have a good asymptotic evaluation despite the truncation. Typically, one can chose 2 times the abscissa of the last jump :

$$
\mathrm{n} \approx 2 /(\exp (\pi / \mathrm{b})-1)
$$

or approximately when $b$ is large enough in front of $\pi$ (which is the case in general) :

$$
\mathrm{n} \approx 2 \mathrm{~b} / \pi
$$

## Table 4

| Parameter b | Rank n |
| :---: | :---: |
| 100 | 63 |
| 250 | 158 |
| 500 | 317 |
| 1000 | 636 |
| 2500 | 1591 |
| 5000 | 3182 |
| 10000 | 6365 |
| 25000 | 15914 |
| 50000 | 31830 |
| 100000 | 63661 |

Roughly speaking, the accuracy of the asymptotic evaluation therefore depends on a linear variation in the number of terms of the truncation with respect to $b$ ( $n \approx 0,6366198 . b$ ).

The graphic below gives the example of $\mathrm{b}=100$.
The reader will therefore note, that this simple previous calculation does not apply to "small" b values ( $b<50$ ) due to the presence of significant oscillations. These particular cases are discussed in Appendix 2.

For the sake of accuracy, all the calculations were conducted with 10000 terms except in the case of $b>100000$ for which we used 100000 terms and even more when specified so.

When, on the contrary, we are interested in areas where the function studied is not subject to a jump but is close to a zero slope, the equation to be solved is $(-1)^{\mathrm{m}} \cdot \cos (\mathrm{b} \cdot \operatorname{Ln}(\mathrm{m})) \approx-(-1)^{\mathrm{m}+1} \cdot \cos (\mathrm{~b} \cdot \operatorname{Ln}(\mathrm{~m}+1))$ and therefore :

$$
\text { b. } \operatorname{Ln}(1+1 / \mathrm{m})) / \pi \approx 2 \mathrm{k}
$$

The corresponding abscissas are :

$$
\mathrm{m} \approx 1 /(\exp (2 . \pi \cdot \mathrm{k} / \mathrm{b})-1)
$$

So that for our example

## Table 5

| k | m |
| :---: | :---: |
| $\ldots$ | $\ldots$ |
| 10 | 243 |
| 9 | 270 |
| 8 | 304 |
| 7 | 347 |
| 6 | 405 |
| 5 | 487 |
| 4 | 608 |
| 3 | 811 |
| 2 | 1217 |
| 1 | 2435 |
| 0 | $+\infty$ |

Let us note that for the sinus, the expressions of the sought abscissas result in exactly the same.
Finally, in view of graphic64, and directly related to the fact of having an alternating sum, the accuracy of the evaluation is subject to oscillations. Thus, the sum $\sum$ is corrected by half of the last term (or equivalently the average of the sum at ranks $\mathrm{n}-1$ and n is made). Eventually, when necessary, the average of several terms in even number is made (up to 100 terms when $b>100000$ ).

## Appendix 2: Case of low value abscissas b.

The range concerned here is before the occurrences of both the first Riemann zero and the first Dirichlet zero. This therefore has no bearing on the conclusions as to the Riemann hypothesis made in this text. However, it is studied for a simple reason : It is an exception to rule $R 2(a, b) \geq-1$ in a clear way.

We mentioned in the previous appendix the vigorous oscillations of functions studied for low $b$ values. An example for $b$ $\approx 1,569(\mathrm{a}=1 / 2)$, is given below. As the reader can see, it is $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ that is subject to the greatest amplitudes. It should also be noted that the example given corresponds to the minimum value of $\mathrm{R} 2(\mathrm{a}=1 / 2, \mathrm{~b})$.

The rule of the $\operatorname{rank} \mathrm{n} \approx 2 /(\exp (\pi / \mathrm{b})-1)$ for the truncation of the sums is no longer suitable (see also appendix 1 ). However, although strong oscillations are perpetuated beyond $n$ equal to 100000 or even 1000000 (based on research not replicated here), a good approximation of the asymptotic value can be found using less than 1000 terms as shown in the data below simply by correcting the last term by half its value.
In fact, our usual 10000 terms are more than necessary.
Table 6

## Appendix 4 : Functions Rk(a,b).

In this appendix, we deviate somewhat from our goal by the fact that we are not only focusing on $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$, but also on the related $\operatorname{Rk}=\operatorname{Rk}(\mathrm{a}, \mathrm{b})$ functions :

$$
\begin{equation*}
\mathrm{R}_{\mathrm{k}}(\mathrm{a}, \mathrm{~b})=\frac{\mathrm{C}_{\mathrm{k}-2}(\mathrm{a}, \mathrm{~b}) \cdot \mathrm{Ck}(\mathrm{a}, \mathrm{~b})+\mathrm{S}_{\mathrm{k}-2}(\mathrm{a}, \mathrm{~b}) \cdot \mathrm{S}_{\mathrm{k}}(\mathrm{a}, \mathrm{~b})}{\left(\mathrm{C}_{\mathrm{k}-1}(\mathrm{a}, \mathrm{~b})\right)^{2}+\left(\mathrm{S}_{\mathrm{k}-1}(\mathrm{a}, \mathrm{~b})\right)^{2}} \tag{39}
\end{equation*}
$$

We thus have :

$$
\begin{align*}
& \mathrm{R} 2(\mathrm{a}, \mathrm{~b})=\frac{\mathrm{C} 0(\mathrm{a}, \mathrm{~b}) \cdot \mathrm{C} 2(\mathrm{a}, \mathrm{~b})+\mathrm{S} 0(\mathrm{a}, \mathrm{~b}) \cdot \mathrm{S} 2(\mathrm{a}, \mathrm{~b})}{(\mathrm{C} 1(\mathrm{a}, \mathrm{~b}))^{2}+(\mathrm{S} 1(\mathrm{a}, \mathrm{~b}))^{2}}  \tag{40}\\
& \mathrm{R} 3(\mathrm{a}, \mathrm{~b})=\frac{\mathrm{C} 1(\mathrm{a}, \mathrm{~b}) \cdot \mathrm{C} 3(\mathrm{a}, \mathrm{~b})+\mathrm{S} 1(\mathrm{a}, \mathrm{~b}) \cdot \mathrm{S} 3(\mathrm{a}, \mathrm{~b})}{(\mathrm{C} 2(\mathrm{a}, \mathrm{~b}))^{2}+(\mathrm{S} 2(\mathrm{a}, \mathrm{~b}))^{2}} \tag{41}
\end{align*}
$$

and so on.
The reader will refer to relationships (14) and (15) for the definition of $\mathrm{Ck}(\mathrm{a}, \mathrm{b})$ and $\mathrm{Sk}(\mathrm{a}, \mathrm{b})$.
In fact, the $k=2$ case, from previous studies, is constituting a kind of initial boundary case. We observe the effect of the increase in power affecting the Napierian logarithm of that starting expression.

The aim is of course to check whether $\operatorname{Rk}(\mathrm{a}, \mathrm{b})$ functions, especially its negative values, can instruct us on the $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$ reference function.

The undulations of the $\operatorname{Rk}(\mathrm{a}, \mathrm{b})$ functions, particularly on the negative values side, are much broader than those of the initial R2( $a, b$ ) function in the $b<20$ zone, recalling that this area (near origin and without adverse impact on the study) is also a source of exceptional behaviour for R2(a,b).

Past the zone of low $b$ values, the $\operatorname{Rk}(a, b)$ functions are getting closer and closer to the horizontal $y=1$ axis as $k$ increases. For large enough $k$, it is therefore likely that any negative value of $\operatorname{Rk}(a, b)$ does exist beyond abscissa $b=20$.

Thus, just as R2 has a minimum (in the order of $-1 / 2$ when $b>5$ ), the minimum of the R 3 function seems to be likely around 0 (excluded in the figures below).

|  |  |
| :---: | :---: |
| $\mathrm{a}=1 / 2, \frac{\text { Graphic } 75}{\mathrm{~b}=7004.5 \text { to } 7005.5}$ | $\mathrm{a}=1 / 2, \mathrm{~b} \stackrel{\text { Graphic 76 }}{=36509.5 \text { to } 36510.5}$ |

## Appendix 5 : Numeric data for $r_{M}$ and $r_{p e a k}$.

The only case of undershooting -0.5 for $\mathrm{R} 2(1 / 2, \mathrm{~b})$ is shown in red font in the table below. The values of the peaks are given as mere indicative information (see Appendix 9).

## Table 8

## Appendix 7 : Cancellation of R2(a,b).

Expression R2(a,b) is null at Riemann and Dirichlet zeroes. However, these are not the only cancellation solutions since the condition to fill is not $\mathrm{C}^{2}+\mathrm{S}^{2}=0$, but $\mathrm{C} 0 . \mathrm{C} 2+\mathrm{S} 0 . \mathrm{S} 2$. The purpose of the graphics below is simply to illustrate the fact that cancellations at critical abscissas of this article generally go in pairs, meaning two abscissas "close" to each other, one abscissa a zero and the other one not.

## Appendix 8 : Functions to approximate $\mathbf{r}_{\text {peak }}$.

A first approximation function relative to the height of the peaks of $\mathrm{R} 2(1 / 2, b)$ values, leading to differences in percentage between the observed values and said measurement function as noted in graphic 82 , obeys to the relationship :

$$
\begin{equation*}
\mathrm{r}_{\text {peak }} \approx 1+\frac{5}{\left(\mathrm{~b}_{\text {peak }}\right)^{1 / 4} \cdot \Delta \mathrm{~b}_{\mathrm{r}}{ }^{2}} \tag{42}
\end{equation*}
$$

The term $\Delta b_{r}$ is the gap between two Riemann's consecutive zeroes surrounding the peak $r_{\text {peak }}$ of $R 2(1 / 2, b)$. The height of the peak thus reacts in a certain way as the inverse of a radiation temperature in relation to the abscissa of the peak (Stefan-Boltzmann law type $b_{\text {peak }} \approx \alpha .\left(1 / r_{\text {peak }}\right)^{4}$ ) and as an energy for the atomic level $\Delta b_{r}$ (law type $r_{\text {peak }} \approx \beta / \Delta b_{r}{ }^{2}$ ).

Graphic82, where Dirichlet's zero abscissas are represented by vertical lines, clearly shows that the error is amplified by the fact that the existence of these zeros is not taken into account at the moment.
Modification below introduced by a second approximation function, and corresponding to graphic83, takes into account this point :

$$
\begin{equation*}
\mathrm{r}_{\text {peak }} \approx 1+\frac{1}{\left(\mathrm{~b}_{\text {peak }}\right)^{1 / 4}}\left(\frac{1.238}{\left(\mathrm{~b}_{\text {peak }}-\text { abs_zeroR- }\right) .\left(\text { abs_zeroR }+-\mathrm{b}_{\text {peak }}\right)}+\frac{-18.1295}{\left(\mathrm{~b}_{\text {peak }}-\text { abs_zeroD- }\right) .\left(\text { abs_zeroD+ }-\mathrm{b}_{\text {peak }}\right)}\right) \tag{43}
\end{equation*}
$$

Close to the origin of b's, the relationship (43) still has errors in the order of $30 \%$ or more. The following relationship, a simple variant of the previous one, improves this point:

$$
\begin{equation*}
\mathrm{r}_{\text {peak }} \approx 1+\frac{3}{\operatorname{Ln}\left(\mathrm{~b}_{\text {peak }}\right)}+\frac{1}{\left(\mathrm{~b}_{\text {peak }}\right)^{1 / 4}}\left(\frac{1.238}{\left(\mathrm{~b}_{\text {peak }}-\text { abs_zeroR- }\right) .\left(\text { abs_zeroR }+-\mathrm{b}_{\text {peak }}\right)}+\frac{-18.1295}{\left(\mathrm{~b}_{\text {peak }}-\text { abs_zeroD-).(abs_zeroD+- } \mathrm{b}_{\text {peak }}\right)}\right) \tag{44}
\end{equation*}
$$

Graphic83still presents errors between the actual values of the peaks and the approximation. We searched for a better version in the form

$$
\begin{equation*}
\mathrm{r}_{\text {peak }} \approx 1+\frac{\gamma}{\operatorname{Ln}\left(\mathrm{b}_{\text {peak }}\right)}+\frac{1}{\left(\mathrm{~b}_{\text {peak }}\right)^{1 / 4}} \sum\left(\frac{\alpha_{i}}{\left(\mathrm{~b}_{\text {peak }}-\text { abs_zeroRi- }\right) .\left(\text { abs_zeroRi+ }-\mathrm{b}_{\text {peak }}\right)}+\frac{\beta_{\mathrm{i}}}{\left(\mathrm{~b}_{\text {peak }}-\text { abs_zeroDi- }\right) .\left(\text { abs_zeroDi }+-\mathrm{b}_{\text {peak }}\right)}\right) \tag{45}
\end{equation*}
$$

taking into account the Riemann and Dirichlet zeros further from the peak. For our part, this does not seem to significantly lessen errors in a general application.

Besides, some relation like

$$
\begin{equation*}
\mathrm{r}_{\text {peak }} \approx 1+\frac{1}{\left(\mathrm{~b}_{\text {peak }}\right)^{1 / 4}} \sum\left(\frac{\alpha_{\mathrm{i}}}{\mid \mathrm{b}_{\text {peak }}-\text { abs_zeros }\left.\right|^{n}}\right) \tag{46}
\end{equation*}
$$

i.e. without associating pairs of zeros, but simply taking into account all the differences between abscissas of the peak and those of the zeros ( n being a power to adapt) seems doomed to failure.

## Appendix 9 : Errors on the peak values of R2(a,b).

The relative error on the actual value of the peaks $\mathrm{R} 2=(\mathrm{C} 0 . \mathrm{C} 2+\mathrm{S} 0 . \mathrm{S} 2) /\left(\mathrm{C} 1^{2}+\mathrm{S} 1^{2}\right)$ has not been specified so far. These peaks of values correspond to situations where $\mathrm{C} 1^{2}+\mathrm{S} 1^{2}$ tends towards 0 at the denominator of the ratio $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$. Numerically, the value of this denominator can be largely distorted in the absence of precaution. As this is obtained using a truncation of the Dirichlet Eta function, it is necessary to ensure a sufficient number of terms to obtain a valid result when the abscissa b increases (see Appendix 1 page 31). The repercussion is all the greater as $\mathrm{C}^{2}+\mathrm{S} 1^{2}$ is smaller. Calculations must be carried out with a suitable truncation. For the production of the tables below, with the Excel tool, we have extended the investigation up to 300000 terms. However, some results for peaks values remain fluctuating in a very significant way.

The graphics below thus give, as a mere information, some data relating to these valuation uncertainties.

The case with the smallest gap between Riemann zeros among the first 500000 of them is then shown below and in the first row of the two previous tables. The magnitude of the discrepancies depending on the truncation chosen is obvious. Note that in our numerical reports in the main text, we used for this example the truncation to 200000 terms (which is not the best).

Comparing these data with those obtained with the Pari gp tool shows that the discrepancies are not due to the imprecision of the spreadsheet. They are mainly related to the choice of truncation. In fact, the confidence limit, say at $10 \%$, already manifests itself around a peak of height between 100 and 200. This means that at 10000 , we are almost at the limit of any kind of reliable appreciation (if we want to stay in a reasonable calculation time). This does not call into question the nature of the formulas proposed in the text for peaks' values but the reader must remain vigilant on this point (which was recalled in our conclusion in the main text). It should be noted, however, that for the minima of $\mathrm{R} 2(\mathrm{a}, \mathrm{b})$, calculation errors are generally of lesser incidence.

The reader will be able to do some tests thanks to underneath programming in Pari gp. He will be able to appreciate for himself the differences of evaluation with Excel spreadsheet as well as the sometimes staggering effect of the truncation. In particular, it can use for the comparison the data in appendix 5(with large discrepancies here or there).

```
{a=-1/2;b=273193.6;
n =100000; \\truncation
c0 = sum(i = 1, n, -((-1)^i)*(i^a)*\operatorname{cos}(\mp@subsup{b}{}{*}\operatorname{log}(\textrm{i})));
c0 = c0-(1/2)*((-1)^(n+1))*(n^a)*\operatorname{cos}(\mp@subsup{b}{}{*}\operatorname{log}(n));
c1 = sum(i = 1, n, ((-1)^i)*(i^a)* 酋(i)*
c1 = c1+(1/2)*((-1)^(n+1))*(n^a)*\operatorname{log}(n)*
c2 = sum(i = 1, n, -((-1)^^)*(i^a)*\operatorname{log}(\textrm{i})*\operatorname{log}(\textrm{i})*\operatorname{cos}(\textrm{b}*\operatorname{log}(\textrm{i})));
c2 = c2-(1/2)*((-1)^(n+1))*(n^a)*\operatorname{log}(n)*\operatorname{log}(n)*\operatorname{cos}(\mp@subsup{b}{}{*}\operatorname{log}(\textrm{n}));
s0 = sum(i = 1, n, -((-1)^i)*(i^a)*sin(b*\operatorname{log}(\textrm{i})));
s0 = s0-(1/2)*((-1)^(n+1))*(n^a)*sin(b*log(n));
s1 = sum(i = 1, n, ((-1)^i)*(i^a)*\operatorname{log}(\textrm{i})*\operatorname{sin}(\textrm{b}*\operatorname{log}(\textrm{i})));
s1 = s1+(1/2)*((-1)^(n+1))*(n^a)*log(n)*sin(b*log(n));
s2 = sum(i = 1, n, -((-1)^i)*(i^a)*\operatorname{log}(\textrm{i})*\operatorname{log}(\textrm{i})*\operatorname{sin}(\mp@subsup{b}{}{*}\operatorname{log}(\textrm{i})));
s2 = s2-(1/2)*((-1)^(n+1))*(n^a)*log(n)*\operatorname{log}(n)*sin(b* log(n));
sc1 = c1*c1+s1*s1;
sc2 = c0*c2+s0*s2;
r2 = sc2/sc1;
print(sc1); print(sc2); print(r2)}
```

When the size of the truncation is insufficient, we may find values of R 2 well below -0.50 as shown by the first calculation below.

```

When the numerator itself is small, in addition to the denominator, a sign inversion of the first one can numerically give a totally aberrant results $\mathrm{R} 2 \ll-1$ if the truncation is not suitable. The reader should pay attention to it for his own trials.

## Appendix 10 : Locus of ( $\mathbf{R} 2 x(a, b), \mathbf{R 2 y}(\mathbf{a}, \mathrm{b}))$.

The graphs below represent R2y as a function of R2x. For each of them, the parameter a is fixed and the represensative points are ( $\mathrm{R} 2 \mathrm{x}(\mathrm{a}, \mathrm{b}), \mathrm{R} 2 \mathrm{y}(\mathrm{a}, \mathrm{b})$ ), b describing the 40000 positions between 0 excluded and 10000 with $1 / 4$ spacing. The goal is to show the evolution according to the choice of a which is a global shift to the left when a increases.

This result is not surprising, the interesting point being here to show the special case of $\mathrm{a}=1 / 2$ whose demarcation lines $R 2 x=0$ and $R 2 y=-1 / 2$, have no equivalent for the other values of $a$, other values giving increasingly blurred boundaries.

We can notice that the points are not necessarily always deported to the left for the right part of the critical line (a<1/2) especially in the area where the Riemann zeros do not yet appear ( $b<4<14$ ). The mix of equations being based on sinusoids it is not surprising to find undulating figures for some of the values of a (here the one close to 0 ) and position's inversions.

The graphs below show the evolution between the minimas around the peak located between the $106073^{\text {th }}$ and the $106074^{\text {th }}$ Riemann zeros ( $b \approx 78974.79335$ and $b \approx 78974.82196$ ). Note before, that the intervals for b as a function of a , forming the minimums of R2 are as follows, the isopleths being here of the type of that of graphic 31 while showing that the herby example is more complex than the basic model :

| a | b |  |
| :---: | :---: | :---: |
|  | abs_r $_{\mathrm{M}^{-}}$ | abs_r $_{\mathrm{M}}{ }^{+}$ |
| 0 | 78974,685273 | 78974,95526 |

| 0,41 | 78974,653390 | 78974,968362 |
| 0,42 | 78974,650501 | 78974,961723 |
| 0,43 | 78974,648114 | 78974,954352 |
| 0,45 | 78974,753824 | 78974,936901 |
| 0,47 | 78974,756795 | 78974,914576 |
| 0,49 | 78974,767718 | 78974,885999 |
| 0,5 | 78974,773018 | 78974,875051 |
| 0,51 | 78974,767028 | 78974,880243 |
| 0,53 | 78974,751497 | 78974,905664 |
| 0,55 | 78974,745422 | 78974,926883 |
| 0,6 | 78974,490328 | 78974,963988 |
| 0,7 | 78974,448655 | 78975,004068 |
| 0,8 | 78974,430485 | 78975,019176 |
| 0,9 | 78974,433970 | 78975,014951 |

As usual, what interests us is the line $\mathrm{R} 2 \mathrm{x}=\mathrm{R} 2 \mathrm{y}$ of the effective solutions of R 2 . This line corresponds at the same time to the minimum values of R2.
In the present case, which is that corresponding to a peak of great magnitude, when parameter a describs the range 0 to 1 , the solutions R2 are, roughly by decreasing values, in the approximate interval [-1.184574789, 0.950381679]. The value $R 2=-1$ is finally reached only when the parameter a exceeds 0.9215 , so quite far from $a=1 / 2$.

## Appendix 11 : R2(a,b) paths.

These graphs represent R2y as a function of R2x between a Riemann zero and its successor. Since $(C 0, S 0)=(0,0)$ for a Riemann zero, this results in $(R 2 x, R y x)=(0,-1 / 2)$ on these abscissas $b=b_{R}$. The trajectory between two zeros thus begins in the graphs below at $(0,-1 / 2)$ and ends at $(0,-1 / 2)$. The direction of the increasing abscissas $b$ is indicated each time. The only relevant solutions, by construction (see body text) are those on the axis $\mathrm{R} 2 \mathrm{x}=\mathrm{R} 2 \mathrm{y}$ which does not hinder us from looking at the curves themselves. The Dirichlet abscissas $b_{D}=k .2 \pi / \operatorname{Ln}(2)$ are represented by purple dots. These points are usually close to the line $R 2 x=R 2 y$ and on a branch sending points to infinity (i.e. two values of $b$ such as C1. S2-C2. S1 = 0).

| Locus R2x/R2y <br> $1^{\text {rst }}$ to $2^{\text {nd }}$ Riemann's zeros <br> $2^{\text {nd }}$ Dirichlet's zero | Locus R2x/R2y |
| :---: | :---: |
| Locus R2x/R2y $3^{\text {rd }}$ to $4^{\text {th }}$ Riemann's zeros $3^{\text {rd }}$ Dirichlet's zero | Locus R2x/R2y $4^{\text {th }}$ to $5^{\text {th }}$ Riemann's zeros |
| Locus R2x/R2y <br> $5^{\text {th }}$ to $6^{\text {th }}$ Riemann's zeros <br> $4^{\text {th }}$ Dirichlet's zero | Locus R2x/R2y $6^{\text {th }}$ to $7^{\text {th }}$ Riemann's zeros |

Now let us take a close-up view of the triangular area that is the most interesting.
We observe two main types of graphs between two Riemann zeros:

- Type 1 when the trajectory includes an even number of divergences due to $\mathrm{C} 1 . \mathrm{S} 2-\mathrm{C} 2 . \mathrm{S} 1=0$.
- Type 2 when the trajectory includes an odd number of divergences due to $\mathrm{C} 1 . \mathrm{S} 2-\mathrm{C} 2 . \mathrm{S} 1=0$.

Note: 1 divergence corresponds to a one-way trip $\pm \infty$ plus a return trip $\mp \infty$.

Appendix 12 : Distribution of $\operatorname{Cos}(\mathbf{b} \cdot \operatorname{Ln}(m))$ and $\operatorname{Sin}(b . \operatorname{Ln}(m))$.
