## Are all integers Lychrel or Cheryl's ?

## Hubert Schaetzel

#### Abstract

When executing Wade VanLandingham's algorithm, palindromy, if it occurs, is not an invaluable achievement, but a mere youth event, a banal incident. The purpose of this article is to give a measure of the gap to palindromy and its evolution during the process in order to justify this cavalier assertion and at the same time show how similar all integers are when subjected to this algorithm. However, what initially seems to be an evidence in base 10 suddenly takes a different turn in base 2, risking to dispute the actual nature of integers in any base and leaving more questions than answers as summarized in the title of the article.

## Les nombres entiers sont-ils tous de Lychrel ou de Cheryl ?

Résumé Lors de l'exécution de l'algorithme de Wade VanLandingham, la palindromie, si elle survient, n'est pas un aboutissement à valeur inestimable, mais un simple évènement de jeunesse, un incident banal. Le but de cet article est de donner une mesure de l'écart à la palindromie et son évolution au cours du processus afin de justifier cette affirmation cavalière et de montrer dans le même temps à quel point tous les nombres entiers se ressemblent lorsque soumis à cet algorithme. Cependant, ce qui semble d'abord être une évidence en base 10 prend soudain un tour différent en base 2 risquant de remettre en cause la nature effective des nombres dans toutes les bases et laissant plus de questions que de réponses comme le résume le titre de l'article.

## 1.Introduction.

The title of the article is a provocative banter. Its meaning, quite elastic, expands or contracts, as this reading progresses.
Wade VanLandingham's algorithm consists of successive additions of a result with its symmetrical. If the operation does not result in a palindrome, the initial number is a Lychrel number. Few theoretical studies are available on this subject. Thus the main source and database used here are those of reference [1].

Years of continuous calculations have been carried out on certain numbers, including the presumed "first one" of them in order to confirm the absence of a palindrome. The research work thus seems to be mainly focused on the brute-force method of launching a program in the hope of setting a record, knowing that the only real record is infinity. Herein we propose to assess the gap with palindromy and gauge within a few tens of seconds the interest of conducting such an investigation. We will show that a massive and prolonged search is doomed to fail regardless of the initial number in the range of number sizes of current records (so for 196 also).

Much greater challenges however hide behind Lychrel which are exposed in paragraph 6.

## 2.Programming preliminaries.

The palindromy gap assessment is based on a VBA-based computer program that can be executed with a simple spreadsheet. The 0 -gap does not stop the program, this event being considered a simple step of calculation of no real importance. The choices of initial number and number of steps of the process are set up at the beginning of the program provided in appendix 1.

The principle of calculation is explained below by an example.
So let us choose the integer 196. We get the succession of numbers of the second column by adding the symmetrical and examine its nature in relation to palindromy.

The term "thread" introduced by Jason Doucette corresponds to a sequence of numbers obtained by this process.

| Steps <br> n | Thread | Symmetric <br> numbers | Associated <br> palindromes | Gaps to <br> palindrome | Measures M <br> $=$ <br> Quantities of 1 <br> within gap |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 196 | 691 |  |  |  |
| 1 | 887 | 788 | 787 | 100 | 1 |
| 2 | 1675 | 5761 | 0575 | 1100 | 2 |
| 3 | 7436 | 6347 | 6336 | 1100 | 2 |
| 4 | 13783 | 38731 | 03773 | 10010 | 2 |
| 5 | 52514 | 41525 | 41514 | 11000 | 2 |
| 6 | 94039 | 93049 | 93039 | 01000 | 1 |
| 7 | 187088 | 880781 | 087078 | 100010 | 2 |
| 8 | 1067869 | 9687601 | 0967769 | 0100100 | 2 |
| 9 | 10755470 | 07455701 | 00745470 | 10010000 | 2 |
| 10 | 18211171 | 17111281 | 1711171 | 01100000 | 2 |
| 11 | 35322452 | 25422353 | 25322352 | 10000100 | 2 |
| 12 | 60744805 | 50844706 | 50744705 | 10000100 | 2 |

The palindrome associated with a given number is first determined by identifying the centre of symmetry of the examined number. Having done so, we then look for the smallest of the two numbers on either side of this centre and retain the smallest of these two which then serves as a substitute in the associated palindrome. A specific treatment of the numbers 1 and 9 is sometimes necessary and the reader will find it integrated into the algorithm attached in appendix 1.

The reader will note that we are looking for a gap to the palindrome necessarily composed only of 0 or 1 and our algorithm is designed accordingly.

We then get the following two graphs, the second being a close-up view near the chart origin of the first one.

The number produced by the algorithm deviates from a palindrome by very few at steps 1,6 and 16 . It then departs following a cloud of points scattering around an average line $y=a \cdot x$ where $a \approx 0.102(x=n, y=M)$. We call this middle line, the line of palindromic camber.

Let us have $\mathrm{M}(\mathrm{n})$ the measure obtained at the iteration n . The graph below shows the evolution of positive or negative differences $M(n)-M(n-1)$. We take samples formed by a set of 100 iterations. For each set $\{100 n, 100(n+1)-1\}$, we get a (negative) minimum and a (positive) maximum. The graph below gives the result of the 500 points provided in this way for the minimums (the sign - is added to the $\operatorname{Min}()$ for comparison to the $\operatorname{Max}()$ ) and 500 points also for the maximums.

We will return to the concern of $\mathrm{M}(\mathrm{n})-\mathrm{M}(\mathrm{n}-1)$ gaps in paragraph 5 with more examples.

## 3.The line of palindromic camber.

## Proposition

The line of palindromic camber is an invariant (in base 10). It is common to all integers.

## Argument

The proposal is based on a very small number of trials, almost all of which are given in this article. Our conviction is strong even if the argument that follows remains rudimentary. However, it is based on the admission that there are no exceptional numbers in base 10 (see paragraph 6) which is by no means a trivial supposition. The gap to palindromy is weakly linked (hence the invariance) to the number initially chosen, but depends largely on the carries (of 1) of each 10figure creating an ever-maintained chaos (hence the point cloud), the number of these carries being strongly linked to the length of the word (hence the average middle line) and the gap to palindromy is linked to the number of carries.
Indeed, let us have $L$ the length of the integer at step $i$. The algorithm acts on the digits 0 to 9 with have average of 4.5. For a large number of iterations, the addition would then increase the value of the number of a ratio $4.5 / 10=0.45$. Fullscale tests appear to indicate a slightly lower ratio of 0.41 . The reader will find in appendix 2 a much more comprehensive study of the $\mathrm{L} / \mathrm{i}$ ratio, as our argument is so far too simplistic.
Let us then have C the number of carries at step i. The probability of carries on the entire length of a large number with another whose digits are taken at random, not forgetting to add the carries each time, is $50 \%$. Doing addition with mirror integers does not change this point if the distribution between digits 0 to 9 is homogenous for the current integer and the probability is the same for this particular algorithm, hence an asymptotic ratio for $\mathrm{C} / \mathrm{L}$ equal to 0.5 . This is true regardless of the base used.
Then let us look at the link between the number of carries and the number of deviations to the palindrome at step i. Let us take an example :

| Initial integer | 11692808688932019641372632460191398978072070 |
| :--- | :--- |
| Mirror integer | 07027087989319106423627314691023988680829611 |
| Carries after addition | 00100011111010011000000001100101111100110000 |
| Addition | 18719896678251126064999947151215387658901681 |
| Palindrome | 18619885678251115064999946051115287658891681 |
| Gap to palindrome | 00100011000000011000000001100100100000010000 |

A carry causes a deviation to the palindrome (highlight in red colour). This has a 1 to 1 effect in the absence of other effects. On the other hand, when carries are on either side of the number (highlight in blue colour), the two do not generate any effect. The relationship is 2 to 0 . For the first type of event occurring twice as often as the second, the overall relationship is $2+2$ versus $2+0$, or $50 \%$. There are of course other effects. For example, if all the digits are greater or equal to 5 , the carries are systematic without destroying the palindromy. But this effect is transient and has no asymptotic consequences. Digital data show approximately a $50 \%$ equilibrium.
That said, the overall balance sheet then boils down to the proposal $\mathrm{M}_{\text {average }} \approx(0.41) \cdot(0.5) \cdot(0.5) \cdot \mathrm{i} \approx 0.102 \mathrm{i}$ which is effectively observed.

## Note

For very large numbers, the point cloud near the origin will obviously be shifted locally (with a positive ordinate at origin). But the asymptotic impact is totally negligible and the average middle line thus returns to its place when we take into account enough data.

## Illustration

We chose the first ten integers : 01 to 010 . The reader will distinguish those with the alternative choice of 1 to 10 , very different, which would give several redundancies since $8,4,2$ are twins to 1 , as 6 to 3 and 10 to 5 in this specific algorithm framework.

In addition (without any special precaution), we chose the ten numbers, with 18 digits, 456987689111798120 to 456987689111798129.

All these numbers have in common the same line of palindromic camber, the data being shifted at the graph origin in the second series of tests as shown in chart 7.

For 18 digits, there are statistically, according to Jason Doucette's website, $90.55 \%$ of Lychrel numbers. Here, the exception corresponding to this $10 \%$ is 45698768911798124 which has a 0 -camber at step 21 (which here is only a happy coincidence).

## 4.The smallest Lychrel number.

Usually, the smallest presumed Lychrel's number is cited as equal to 196. The reader is invited to open the territory to " 097 " which gives the same succession of numbers as " 196 ", and is therefore his perfect smallest "twin":

| Steps <br> N | Thread | Symmetric <br> numbers | Associated <br> palindromes | Gaps to <br> palindrome | Measures M <br> Quantities of 1 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 097 | 790 |  |  |  |
| 1 | 887 | 788 | 787 | 100 | 1 |
| 2 | 1675 | 5761 | 0575 | 1100 | 2 |
| $\ldots$ | $\ldots$ | $\ldots$ | $\ldots$ | $\ldots$ | $\ldots$ |

## 5.The atypical numbers.

We name atypical those numbers whose particularity is to present a palindrome a little later than the others integers. The reader will be able to judge underneath by himself the extent of this deviation from the general pattern visible in the evolution of the point clouds subsequent to a 0 -gap event.

For these records, the evolution of M at respective steps 288 and 289 is on either side $36 \downarrow 0 \nearrow 38$. Although remarkable near origin, these changes are minor for more advanced iterations and become commonplace as suggested by another example (that of the initial number "196") given by graph 3 . For this case quite standard, the first occurrence of more than -36 is at iteration $1132(132 \searrow 90:-42)$. The occurrence greater than or equal to +38 occurs at iteration 1390 (128 166 $:+38$ ). Over 3000 iterations, positive or negative differences of more than 40 are common.
For Anton Stefanov's example, the first negative overtaking is at iteration $970(126 \searrow 78:-48)$ and the first positive catching-up at step 971 (78 $120:+42$ ).

The graph below, a close-up view of the previous one, shows the subtle kinship of Rob van Nobelen and Anton Stefanov's records.

## 6.The exceptional numbers.

So far we looked at integers for which the linear evolution in size, number of carries and gap to palindromy was subject to a clear additional random part. For these, it seems that they all share the same growth speeds of the so-called size, number of carries and gap to palindromy around expected averages.

It turns out, however, that some numbers have totally predictable behaviours in relation to these three criteria (no random part). Panurge sheeps, they are totally different from their congeners, partially left to their misdirections. We do not know if they exist in base 10, but their presence is detected here in base 4 and 2 . We call them Cheryl numbers or exceptional numbers.

Case 1:
Base 4. Initial number : 2211101

| Steps | Thread | Palindromes | Gap to <br> palindrome | Sizes <br> L | \# Carries <br> C | Measures <br> M |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 221112 | 211112 | 10000 | 6 |  | 1 |
| 1 | 1032300 | 0032300 | 1000000 | 7 | 3 | 1 |
| 2 | 1131201 | 1021201 | 110000 | 7 | 3 | 2 |
| 3 | 2213112 | 2113112 | 100000 | 7 | 2 | 1 |
| 4 | 10332300 | 00322300 | 10010000 | 8 | 4 | 2 |
| 5 | 11322201 | 10222201 | 1100000 | 8 | 4 | 2 |
| 6 | 2221112 | 21111112 | 1100000 | 8 | 4 | 2 |
| 7 | 103323000 | 003222300 | 100100100 | 9 | 4 | 3 |
| 8 | 110312301 | 103212301 | 1100000 | 9 | 4 | 2 |
| 9 | 220131312 | 213131312 | 1000000 | 9 | 3 | 1 |
| 10 | 1033323000 | 0032222300 | 1001100100 | 10 | 5 | 4 |
| 11 | 1103222301 | 1032222301 | 11000000 | 10 | 5 | 2 |
| 12 | 2202111312 | 2131111312 | 11000000 | 10 | 5 | 2 |
| 13 | 10333230000 | 00322222300 | 10011001100 | 11 | 5 | 5 |
| 14 | 11003123301 | 10332123301 | 11000000 | 11 | 5 | 2 |
| 15 | 22001313312 | 21331313312 | 1000000 | 11 | 4 | 1 |
| 16 | 103333230000 | 003222222300 | 100111001100 | 12 | 6 | 6 |
| 17 | 110032223301 | 103322223301 | 110000000 | 12 | 6 | 2 |
| 18 | 22002113312 | 213311113312 | 110000000 | 12 | 6 | 2 |
| 19 | 1033332300000 | 003222222300 | 1001110011100 | 13 | 6 | 7 |
| 20 | 1100031233301 | 1033321233301 | 110000000 | 13 | 6 | 2 |

Here the evolution of the initial integer follows a modulo 6 pattern. The values in brackets underneath correspond for the first bracket to the digit present in the studied number and for the latter bracket to the quantity of these identical in-a-row digits. For example, for $\mathrm{i}=18$, we have $(2,2),(0, i / 6-1),(2,1),(1,3),(3, i / 6-1),(1,1),(2,1)$ which gives $(2,2),(0,2),(2,1)$, $(1,3),(3,2),(1,1),(2,1)$ and then $(22),(00),(2),(111),(33),(1),(2)$, or by putting things together 220021113312.

| Steps i | Integers |
| :---: | :---: |
| 6 | 22211112 |
| 12 | 2202111312 |
| 18 | 220021113312 |
| $\mathrm{i}=0 \mathrm{mod} 6$ | $(2,2),(0, \mathrm{i} / 6-1),(2,1),(1,3),(3, \mathrm{i} / 6-1),(1,1),(2,1)$ |
| 1 | 1032300 |
| 7 | 103323000 |
| 13 | 10333230000 |
| $\mathrm{i}=1 \bmod 6$ | $(1,1),(0,1),(3,(\mathrm{i}-1) / 6+1),(2,1),(3,1),(0,(\mathrm{i}-1) / 6+2)$ |
| 2 | 1131201 |
| 8 | 110312301 |
| 14 | 11003123301 |
| $\mathrm{i}=2 \bmod 6$ | $(1,2),(0,(\mathrm{i}-2) / 6),(3,1),(1,1),(2,1),(3,(\mathrm{i}-2) / 6),(0,1),(1,1)$ |
| 3 | 2213112 |
| 9 | 220131312 |
| $\mathrm{i}=3 \bmod 6$ | $(2,2),(0,(\mathrm{i}-3) / 6),(1,1),(3,1),(1,1),(3,(\mathrm{i}-3) / 6),(1,1),(2,1)$ |
| 4 | 10332300 |
| 10 | 1033323000 |
| 16 | 10333230000 |
| $\mathrm{i}=4 \bmod 6$ | $(1,1),(0,1),(3,(\mathrm{i}-4) / 6+2),(2,1),(3,1),(0,(\mathrm{i}-4) / 6+2)$ |
| 5 | 11322201 |
| 11 | 1103222301 |
| 17 | 10032223301 |
| $\mathrm{i}=5 \bmod 6$ | $(1,2),(0,(\mathrm{i}-5) / 6),(3,1),(2,3),(3,(\mathrm{i}-5) / 6),(0,1),(1,1)$ |

So, we have for the three studied items :

$$
\begin{align*}
& \mathrm{L}=6+\operatorname{int}((\mathrm{i}+2) / 3) \approx \mathrm{i} / 3  \tag{1}\\
& \mathrm{C}=\operatorname{if}(\mathrm{i}=3 \bmod 6,1+\operatorname{int}((\mathrm{i}+5) / 6), 3+\operatorname{int}((\mathrm{i}+2) / 6)) \approx \mathrm{i} / 6  \tag{2}\\
& \mathrm{M}=\operatorname{if}(\mathrm{i}=1 \bmod 3, \operatorname{int}((\mathrm{i}+2) / 3), \operatorname{if}(\mathrm{i}=3 \bmod 6,1,2)) \approx \operatorname{or}(\mathrm{i} / 3, \approx 0) \tag{3}
\end{align*}
$$

The remarkable point, apart from the entire predictability, is the round trip between a totally distorted palindrome and near-perfect palindrome, regardless of the size of the current number.

If instead of starting from the "exceptional" number 221112, we start from the "ordinary" number 211112, we have the quite different :

$$
\begin{align*}
& L \approx 0,47 . i  \tag{4}\\
& C \approx 0,23 . i  \tag{5}\\
& M \approx 0,11 . i \tag{6}
\end{align*}
$$

Case 2 :
Base 2.
It seems that this base is mainly home to exceptional numbers, namely, a reproducible phase usually begins after a finite number of steps. This phase responds to the following formulas :

$$
\begin{align*}
& \mathrm{L}=\mathrm{v} 1+\operatorname{int}((\mathrm{i}+\mathrm{v} 2) / 2) \approx \mathrm{i} / 2  \tag{7}\\
& \mathrm{C}=\operatorname{int}((\mathrm{i}+\mathrm{v} 3) / 4)+\mathrm{if}(\mathrm{i}=0 \bmod 4, \mathrm{v} 4, \operatorname{if}(\mathrm{i}=1 \bmod 4, \mathrm{v} 5, \mathrm{if}(\mathrm{i}=2 \bmod 4, \mathrm{v} 6, \mathrm{v} 7))) \approx \mathrm{i} / 4  \tag{8}\\
& \mathrm{M}=\operatorname{int}((\mathrm{i}+\mathrm{v} 8) / 4)+\mathrm{if}(\mathrm{i}=0 \bmod 4, \mathrm{v} 9, \mathrm{if}(\mathrm{i}=1 \bmod 4, \mathrm{v} 10, \mathrm{if}(\mathrm{i}=2 \bmod 4, \mathrm{v} 11, \mathrm{v} 12))) \approx \mathrm{i} / 4 \tag{9}
\end{align*}
$$

For example, the (fixed) settings are ( $\mathrm{i}=0$ for the initial number), with the reproducible phase starting at the i value given in the "Reprod" column :

| Initial number | Reprod. | v 1 | v 2 | v 3 | v 4 | v 5 | v 6 | v 7 | v 8 | v 9 | v 10 | v 11 | v 12 |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 10 | $\mathrm{i} \geq 20$ | 6 | 0 | 12 | 0 | 0 | 0 | -1 | 4 | 0 | -2 | 0 | 0 |
| 100 | $\mathrm{i} \geq 8$ | 5 | 0 | 12 | -1 | -2 | 0 | 0 | 4 | -1 | -1 | 0 | -2 |
| 1000 | $\mathrm{i} \geq 18$ | 7 | 0 | 12 | 0 | -1 | 1 | 1 | 4 | 0 | 0 | 1 | -1 |
| 10000 | $\mathrm{i} \geq 171$ | 32 | 0 | 64 | 1 | 3 | -1 | -4 | 20 | 0 | -6 | -2 | -2 |
| 100000 | $\mathrm{i} \geq 18$ | 9 | 0 | 12 | 1 | 0 | 2 | 2 | 4 | 1 | 1 | 2 | 0 |
| 1000000 | $\mathrm{i} \geq 12$ | 10 | 0 | 12 | 0 | 3 | 1 | 0 | 4 | 2 | -1 | 1 | 2 |
| 10000000 | $\mathrm{i} \geq 12$ | 11 | 0 | 12 | 2 | 1 | 3 | 3 | 4 | 2 | 2 | 3 | 1 |
| 100000000 | $\mathrm{i} \geq 38$ | 13 | 0 | 12 | 3 | 2 | 4 | 4 | 4 | 3 | 3 | 4 | 2 |
| 10000000000 | $\mathrm{i} \geq 22$ | 15 | 0 | 12 | 4 | 3 | 5 | 5 | 4 | 4 | 4 | 5 | 3 |
| 100000000000 | $\mathrm{i} \geq 60$ | 20 | 0 | 36 | 0 | -2 | 2 | 3 | 20 | 0 | 0 | 1 | -1 |
| 1000000000000 | $\mathrm{i} \geq 22$ | 17 | 0 | 32 | 0 | -1 | 1 | 1 | 12 | 0 | 0 | 1 | -3 |
| 10000000000000 | $\mathrm{i} \geq 22$ | 18 | 0 | 36 | -1 | -3 | 1 | 2 | 20 | -1 | -1 | 0 | -2 |
| 100000000000000 | $\mathrm{i} \geq 22$ | 19 | 0 | 32 | 1 | 0 | 2 | 2 | 12 | 1 | 1 | 2 | -2 |
| 1000000000000000 | $\mathrm{i} \geq 22$ | 20 | 0 | 36 | 0 | -2 | 2 | 3 | 20 | 0 | 0 | 1 | -1 |
| 1000000000000000 | $\mathrm{i} \geq 22$ | 21 | 0 | 32 | 2 | 1 | 3 | 3 | 12 | 2 | 2 | 3 | -1 |
| 10000000000000000 | $\mathrm{i} \geq 24$ | 22 | 0 | 36 | 1 | -1 | 3 | 4 | 20 | 1 | 1 | 2 | 0 |
| 1000000000000000000 | $\mathrm{i} \geq 26$ | 23 | 0 | 32 | 3 | 2 | 4 | 4 | 12 | 3 | 3 | 4 | 0 |
| 10000000000000000000 | $\mathrm{i} \geq 28$ | 24 | 0 | 36 | 2 | 0 | 4 | 5 | 20 | 2 | 2 | 3 | 1 |

Integers such as the reproducible phase manifests from the beginning ( $\mathrm{i} \geq 1$ ) are in order of appearance :
10000111, 10100011, 11000101, 11100001, 100010111, 100101100, 101010011, 101101000, 110010101, 111010001, 1000000111, 1000001111, 1001000111, 1001011100, 1001101100, 1010000011, 1010001011, 1011000011, 1011011000, 1011101000, 1100000101, 1100001101, 1101000101, 1110000001, 1110001001, 1111000001.

This is the complete list of numbers of size 10 or less. These numbers converge on only two threads. Of the 26 , the following 4 converge on the second thread :
$1000000111,1010000011,1100000101,1110000001$.

Among the ordinary numbers, more difficult to find (but not necessarily less dense in N ), we have a priori (that is to say for sure as far as $\mathrm{i}=10000$ ) the following numbers :

In the case of chart 13 , the three initial numbers given here all evolve within the same thread. The second graph is a priori another thread (it is at least until step 10000). The growth parameters, on the other hand, are asymptotically identical.

$$
\begin{align*}
& \mathrm{L} \approx 0,57 . \mathrm{i}  \tag{10}\\
& \mathrm{C} \approx 0,28 . \mathrm{i}  \tag{11}\\
& \mathrm{M} \approx 0,13 . \mathrm{i} \tag{12}
\end{align*}
$$

The standard deviations to the average middle line are much larger here than in the case of base 10 .
Of the first 1000 integers in base 2 ( 1 to 111110101000 ), there are only 41 "normal" numbers all listed below :

| 100001111 | 101001100 | 110100101 | 1000101111 | 1010111000 | 1101010101 |
| :--- | :--- | :---: | :---: | :---: | :---: |
| 100011011 | 101011000 | 110110001 | 1000111100 | 1011001100 | 1101100101 |
| 100011100 | 101100011 | 111001001 | 1001010111 | 1011010011 | 1110011001 |
| 100100111 | 101100100 | 111100001 | 1001100111 | 1011100011 | 1110101001 |
| 100110011 | 101110000 | 1000000000 | 1001110100 | 1011110000 | 111010001 |
| 100110100 | 110001101 | 1000000001 | 1010011011 | 1100011101 | 111100001 |
| 101001011 | 110011001 | 1000011111 | 1010101011 | 1100101101 |  |

All of these numbers converge on the same thread.

## 7.Conclusion.

It seems to us that the question of the existence of Lychrel numbers is a relatively minor point in the study of the addition of a number with its mirror number.

Indeed, we can propose two standard questions, stemming from the end of this study, that replicate and whose character seems to us deeper and more fundamental :

- What is the density of Cheryl's integers (or exceptional numbers) in N in base 2?
- Are all integers Cheryl's integers in base 2?
- What is the density of Cheryl's integers in N in base 4?
- Are all integers Cheryl's integers in base 4?
- What is the density of Cheryl's integers in N in base 10 ?
- Are all integers Cheryl's integers in base 10 ?
- What is the density of Cheryl's integers in N in base X ?
- Are all integers Cheryl's integers in base X?

Indeed, the large number of exceptional type integers in base 2 may suggest that during its growth, an ordinary number is likely to meet an exceptional number and thus changes its growth regime up to infinity. This would then mean the total absence of an ordinary number in this base. If this is indeed the case, this property is likely to be the rule in all bases, even if the accessible data seems to say so far quite the opposite !

## Appendix 2 : Speed of growth in the size of an integer.

We evaluate the $L / i$ ratio of the size $L$ of an integer, i.e. the number of its digits, to the current iteration number $i$ of the Wade VanLandingham algorithm. We assume a single asymptotic L/i growth rate for a given base. The data collected are thus those starting with integer " 1 " systematically and are presented below.

The k range, on which the k -average is made, is that of the 1000 iterations between the iteration $\mathrm{i}=1000 . \mathrm{k}$ and the iteration $\mathrm{i}=1000 .(\mathrm{k}+1)-1$ included. The same goes for the assessment of minimums and maximums.

Note here that 1 is an exceptional number in base 2. It is therefore not relevant to compare the data corresponding to the other evaluations. Therefore, they are not included in the graph below.

The base comparison is interesting if its understanding makes it possible to find the exact asymptotic value of the L/i ratio. However, the data only reinforce here confusion as a result of the mysterious reversal of the ratio between base 9 and 10 .

Another approach is to examine the growth mechanism in more detail. This is largely related to the value of the extreme digits of the series of integers obtained by symmetrical addition.

So, in base 10 , it is interesting to examine the distribution of digits $0,1,2, \ldots 9$ to the right and $1,2, \ldots, 9$ to the left of the current integer. Several tests based on different initial numbers (here 193 to 197) show that these distributions do not (presumably) depend on the said initial number (for "normal" numbers), what is expected.

The evolution of the population of each digit-class (0 to 9) is somewhat linear as shown in the graphs below. This is expected.
On the other hand, the expected existence, except for 1 on the left which must logically be the majorant in terms of quantity, of an equiprobable distribution between the different digits is not the effective case. Digits 8 and 9 are more common (except 1 ) on the left, while 7 and 8 are more common on the right.

By crossing the percentages of the distributions of the digits 1 to 9 on the left with those 0 to 9 on the right, an approximate value of the length growth factor $L$ is obtained by summing up the percentages for which the sum of the two digits on the left and right is greater than or equal to 10 . The table below highlights the terms to add :

|  | Left digits | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Right <br> digits | Right mean | $46,66 \%$ | $4,10 \%$ | $4,98 \%$ | $6,10 \%$ | $5,78 \%$ | $3,81 \%$ | $5,59 \%$ | $10,31 \%$ | $12,67 \%$ |
| 0 | $5,78 \%$ | $2,70 \%$ | $0,24 \%$ | $0,29 \%$ | $0,35 \%$ | $0,33 \%$ | $0,22 \%$ | $0,32 \%$ | $0,60 \%$ | $0,73 \%$ |
| 1 | $6,86 \%$ | $3,20 \%$ | $0,28 \%$ | $0,34 \%$ | $0,42 \%$ | $0,40 \%$ | $0,26 \%$ | $0,38 \%$ | $0,71 \%$ | $\mathbf{0 , 8 7 \%}$ |
| 2 | $9,14 \%$ | $4,27 \%$ | $0,37 \%$ | $0,46 \%$ | $0,56 \%$ | $0,53 \%$ | $0,35 \%$ | $0,51 \%$ | $\mathbf{0 , 9 4 \%}$ | $\mathbf{1 , 1 6 \%}$ |
| 3 | $7,84 \%$ | $3,66 \%$ | $0,32 \%$ | $0,39 \%$ | $0,48 \%$ | $0,45 \%$ | $0,30 \%$ | $\mathbf{0 , 4 4 \%}$ | $\mathbf{0 , 8 1 \%}$ | $\mathbf{0 , 9 9 \%}$ |
| 4 | $9,24 \%$ | $4,31 \%$ | $0,38 \%$ | $0,46 \%$ | $0,56 \%$ | $0,53 \%$ | $\mathbf{0 , 3 5 \%}$ | $\mathbf{0 , 5 2 \%}$ | $\mathbf{0 , 9 5 \%}$ | $\mathbf{1 , 1 7 \%}$ |
| 5 | $8,86 \%$ | $4,13 \%$ | $0,36 \%$ | $0,44 \%$ | $0,54 \%$ | $\mathbf{0 , 5 1 \%}$ | $\mathbf{0 , 3 4 \%}$ | $\mathbf{0 , 5 0 \%}$ | $\mathbf{0 , 9 1 \%}$ | $\mathbf{1 , 1 2 \%}$ |
| 6 | $12,53 \%$ | $5,85 \%$ | $0,51 \%$ | $0,62 \%$ | $\mathbf{0 , 7 6 \%}$ | $\mathbf{0 , 7 2 \%}$ | $\mathbf{0 , 4 8 \%}$ | $\mathbf{0 , 7 0 \%}$ | $\mathbf{1 , 2 9 \%}$ | $\mathbf{1 , 5 9 \%}$ |
| 7 | $16,61 \%$ | $7,75 \%$ | $0,68 \%$ | $\mathbf{0 , 8 3 \%}$ | $\mathbf{1 , 0 1 \%}$ | $\mathbf{0 , 9 6 \%}$ | $\mathbf{0 , 6 3 \%}$ | $\mathbf{0 , 9 3 \%}$ | $\mathbf{1 , 7 1 \%}$ | $\mathbf{2 , 1 0 \%}$ |
| 8 | $17,81 \%$ | $8,31 \%$ | $\mathbf{0 , 7 3 \%}$ | $\mathbf{0 , 8 9 \%}$ | $\mathbf{1 , 0 9 \%}$ | $\mathbf{1 , 0 3 \%}$ | $\mathbf{0 , 6 8 \%}$ | $\mathbf{1 , 0 0 \%}$ | $\mathbf{1 , 8 4 \%}$ | $\mathbf{2 , 2 6 \%}$ |
| 9 | $5,33 \%$ | $\mathbf{2 , 4 9 \%}$ | $\mathbf{0 , 2 2 \%}$ | $\mathbf{0 , 2 7 \%}$ | $\mathbf{0 , 3 2 \%}$ | $\mathbf{0 , 3 1 \%}$ | $\mathbf{0 , 2 0 \%}$ | $\mathbf{0 , 3 0 \%}$ | $\mathbf{0 , 5 5 \%}$ | $\mathbf{0 , 6 7 \%}$ |

The double-framed total is $100 \%$ while the highlighted percentages add up to $40.13 \%$, thus a ratio of 0.401 to be compared to 0.413 the average of the values obtained above (page 16). The difference is due to the contribution of second ranked carries. This contribution is in the order of magnitude of $1 \%$.

When the base is smaller, the alignment of values is more delicate.
For example, in base 4, we have the following distributions :

| Left side | 0 | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: |
| $\# 1$ | $/$ | $64,4 \%$ | $28,7 \%$ | $6,92 \%$ |

| Right side | 0 | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: |
| $\# 1$ | $28,7 \%$ | $31,4 \%$ | $24,8 \%$ | $15,0 \%$ |

The crossboard gives :

|  | Left digits | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: |
| Right <br> digits | Right mean | $64,4 \%$ | $28,7 \%$ | $6,92 \%$ |
| 0 | $28,7 \%$ | $18,5 \%$ | $8,2 \%$ | $2,0 \%$ |
| 1 | $31,4 \%$ | $20,2 \%$ | $9,0 \%$ | $\mathbf{2 , 2 \%}$ |
| 2 | $24,8 \%$ | $16,0 \%$ | $\mathbf{7 , 1 \%}$ | $\mathbf{1 , 7 \%}$ |
| 3 | $15,0 \%$ | $\mathbf{9 , 7 \%}$ | $\mathbf{4 , 3 \%}$ | $\mathbf{1 , 0 \%}$ |

The double-framed total is $100 \%$ while the highlighted percentages add up now to $26.1 \%$, thus a ratio of 0,261 to be compared to 0.465 , the average of the values obtained above (page 16). The difference can be explained by the contribution of the second ranked carries, which is absolutely no longer negligible here.
